Removal of Injurious Telegraphs.—14. In case any telegraph post, wire, or telegraphic appliance used or intended to be used as part of or in connection with the telegraphs of the company, or the working or user of any such post, wire, or appliance shall, in the opinion of the Engineer-in-Chief for the time being of the Post Office, certified by writing under his hand, directly or indirectly damage or interfere with the efficient or convenient maintenance, working, or user of any telegraph post wire or telegraphic appliance of the Postmaster-General for the time being existing, or expose any such post, wire, or appliance to risk of damage or to risk of interference with the efficient or convenient working or user thereof, the Company shall, within 24 hours after service on them of a notice in writing by the Postmaster-General, complaining of such damage or interference or apprehended damage or interference, either remove the post or posts, wire or wires, or telegraphic appliance or appliances complained of in such notice, or refix, alter, or repair the same to the satisfaction of the engineer-in-chief for the time being of the Post Office, and if the Company shall make default in so doing within the time aforesaid it shall be lawful for the Postmaster General to remove, alter, or repair the post or posts, wire or wires, or telegraphic appliance or appliances complained of in such notice, and the Company shall, on demand, pay to the Postmaster-General the cost of any removal, alteration, or repair by the Postmaster-General of the posts, wires, and telegraphic appliances complained of in such notice or any of them.

Clause 15 requires the company to pay for any damage done by their wires or appliances to the property of the Postmaster-General.

Provisions for Determination of License on Breach of Contract.—16. In case any sum of money which ought to be paid by the company to the Postmaster-General under or by virtue of these presents shall be in arrear and unpaid for one calendar month after the time at which the same ought to be paid under or by virtue of the covenants herein contained, or in case of any breach, non-observance, or non-performance by or on the part of the company of any of the covenants (other than a covenant for the payment of money) or conditions herein contained, and on the part of the company to be observed and performed, then, and in any such case, the Postmaster-General may, by writing under his seal, revoke and determine the licenses, powers, and authorities hereinbefore granted, and each and every of them, and thereupon the said licenses, powers, and authorities, and each and every of them shall absolutely cease, determine, and become void. Provided always that no such revocation or determination as afore-

Digitized by Google

said shall prejudice or affect any right of action or remedy which shall have accrued, or shall thereafter accrue, to either of the parties hereto under the covenants herein contained.

Power to Postmaster-General to purchase Company's Telegraphs.—17. The Postmaster-General may at any time by six calendar months' previous notice in writing, terminating on the 31st day of December, 1890, or on the 31st day of December, 1897, or on the 31st day of December, 1904, signify to the company his intention to purchase the business of the company; with respect to which this agreement is entered into, and if any such notice be given, the company shall sell and convey, and the Postmaster-General shall purchase all the telegraphs of the company worked under the provisions of these presents, and all the rights, powers, privileges, works, and other property of the company appurtenant to or forming part of such business, and the particulars of the property to be comprised in and the price to be paid by the Postmaster-General for such purchase shall, in case of difference, be determined by arbitration as hereinafter provided.

Arbitration.—18. All matters which in pursuance of the stipulations hereinbefore contained are to be determined by arbitration shall be referred to and determined by the award or awards of a single arbitrator, pursuant to and so as with regard to the mode and consequences of the reference and in all other respects to conform to the provisions of the common Law Procedure Act, 1854, or any then subsisting statutory modification or re-enactment thereof for the time being in force, and the arbitrator on any such reference shall have power to examine witnesses upon oath or affirmation or otherwise, and either to fix, settle, and determine the amount of costs and expenses of and incidental to the reference and award to be paid by both parties or by either party, or to direct the same to be taxed as between solicitor and client or otherwise, or to be settled by any other person or persons, and to direct and award when and by and to whom such costs and expenses respectively shall be paid, and these presents shall be deemed to be a submission to arbitration within the last-mentioned Act, or any such modification or re-enactment thereof as aforesaid, and may upon the application of either party to any reference thereunder and without notice to the other of them to be made by a rule or order of any division of Her Majesty's High Court of Justice.

Agreement not to Affect Postmaster-General's Rights.—19. Nothing in these presents contained shall prejudice or affect the right of the Postmaster-General from time to time to establish, extend, maintain, and work any system or systems of telegraphic communication (whether of a like nature to the aforesaid business of the company or otherwise) in such manner as he shall in his discretion think fit, neither shall anything herein contained prejudice or affect the right of the Postmaster-General from time to time to enter into agreements for, or to grant licenses relative to, the working and user of telegraphs (whether of a like nature to those worked and used by the company or otherwise) or the transmission of telegrams in any part of the United Kingdom with or to any company, person, or persons whomsoever upon such terms as he shall in his discretion think fit. And nothing herein contained shall be deemed to authorise the company to exercise any of the powers or authorities conferred on or acquired by the Postmaster-General by or under the Telegraph Acts, or any of them.

The remaining clauses are merely formal.

LABORATORY NOTES ON ALTERNATING-CURRENT CIRCUITS.*

BY PROFS. W. E. AYRTON, F.R.S., AND JOHN PERRY, F.R.S.

(Concluded from page 195.)

A Shunt Transformer.

The following problem presented itself to our student, Mr. Smith, whose name we have just mentioned; and as his solution depends on the lag produced by self-induction, we have thought that this may be a fitting opportunity for bringing the matter forward. The problem is as follows:—If a certain alternate potential difference be maintained between two mains, M M (Fig. 2), between which there are two incandescent lamps, P and Q, is it possible to make the sum of the mean potential differences maintained at the terminals of the lamps greater than the mean potential difference maintained between the mains without disconnecting the lamps from the mains and inserting an ordinary transformer? For example, suppose that the mean potential difference between the lamps be 100 volts, and it requires a mean potential difference of 55 volts to be maintained between the terminals of each lamp to make it glow properly, can this result be attained without disconnecting the lamps from the mains?

Let 1 1 1 1 (Fig. 3) represent the curve of impressed potential difference; then this may be regarded as being composed of two coincident curves, 1 2, 1 2, the ordinates of which are each exactly half the corresponding ordinates of the original curve 1 1 1 1. Now let it be possible to retard one of the smaller curves and accelerate the other so that they take some position like 3 3 3 3 and 4 4 4 4 (Fig. 4); then, since the sum of the corresponding ordinates of these two curves is equal to the corresponding ordinates of the original curve, it follows that *the mean value of the ordinates of each of these curves must be greater than half the mean value of the ordinates of the original curve.* Mr. Smith's view was, if one of the lamps, P, were shunted with a high resistance possessing much self-induction (Fig. 5), and the other lamp, Q, with a non-inductive high resistance, the wave of potential difference at the terminals of P would be accelerated, while that at the terminals of Q would be retarded, as shown in Fig. 4; hence the result would be that the brightness of the two lamps would be increased by the application of the high-resistance inductive shunt and the high-resistance non-inductive shunt—a result which experiment shows to be correct.

It will probably be objected to this solution that it cannot be employed without introducing a large waste of power, and therefore can have no practical value. But exactly the same objection was raised some years ago to the employment of the ordinary transformer. And just as the practical importance of using transformers has led to such improvements being made in them that the waste of power introduced by their use is far more than compensated for by the economy they introduce into electric distribution, so in the same way is it not possible that Mr. Smith's solution may be so improved that the gain in power arising from working incandescent lamps at their best efficiency may more than compensate for the loss of power in his "shunt transformer"?

On the Effect of Self-Induction in Destroying Ripples.

In the discussion on Mr. Kapp's paper, and on former occasions, we have described to the Society the effect of self-induction in causing the current in an alternating-current circuit to become more and more a sine function of the time. We assumed, of course, that there was a fixed self-induction of the circuit, and we were not considering the possibility of the presence of iron making the self-induction vary, as we know that it does. We have stated that the minor ripples or harmonics never wholly disappear.

We must refer our readers to the *Journal* of the Institution for the elaborate mathematical investigation which follows. The result arrived at is that "hence if the E.M.F. does not follow truly a sine function of the time, the current, although it may be made more nearly a sine function of the time, cannot truly become so, however great the self-induction may be." As an example a case is taken which is "probably the most discontinuous periodic function which we can imagine as occurring in practice. That is, let us imagine the E.M.F. at time O, to have suddenly increased from $-V$ to $+V$,

At time $t=\frac{T}{2}$ to suddenly diminish from V to $+V$.

At time $t=T$ to suddenly diminish from $-V$ to $+V$,

and so on, remaining constant except at times O, $\frac{T}{2}$, T, $\frac{3T}{2}$, 2 T, &c."

It is then shown that "as $\frac{L}{Tr}$ gets greater and greater the current tends more and more to follow the law indicated by the curve—or, rather, straight line—shown in Fig. 6; and this is the nearest approach to a sine function which the current can attain to with such a discontinuous E.M.F. as we have taken."

We give another rather discontinuous periodic function as an example. We assume that the E.M.F. varies in the way shown on Fig. 6.

We have drawn the curves representing C for the values of $\frac{L}{Tr}=0$, 0·01, and 0·1 in Fig. 7, the distance A E representing T, the periodic time.

A B C D E shows current when $\frac{L}{Tr}=0$;

A′ B′ C′ D′ E′ ,, ,, ,, $\frac{L}{Tr}=\cdot1$;

A″ B″ C″ D″ E″ ,, ,, ,, $\frac{L}{Tr}=1$.

The ordinates of this last curve (for $\frac{L}{Tr}=1$) have been magnified ten times.

It is evident that even when E is such a very discontinuous function as this, a moderate amount of self-induction makes the current what is very nearly a pure sine function of the time.

Electric Frequency Meter.

Some time ago one of us suggested, during a discussion on transformers, that a method might be used for analysing an alternate-current wave which somewhat resembled the employment of Helmholtz's resonators for analysing a complex sound vibration. The method then proposed consisted in sending through one of the coils of a dynamometer the current to be analysed, and through the

other an alternate current of known frequency, and varying the frequency of the test current until an attraction was observed between the two coils. The smallest frequency of the test current that will produce such an attraction gives the fundamental rate of alternation of the current which is being analysed, and the magnitude of the attraction between the two coils of the dynamometer the amplitude of the fundamental rate of alternation. The frequency of the test current is then gradually increased until an attraction is again observed between the dynamometer coils, from which the frequency and amplitude of the first higher rate of alternation is determined, and so on for all the component vibrations.

This method has been used with a certain amount of success by Messrs. Lamb and E. W. Smith, at the Central Institution, for the analysis of the current produced by the Ferranti machine. Previous experiments had shown us that this current was not a simple sine function of the time, as the curve rises less rapidly and falls less rapidly than a true sine curve. The difference, however, between the two is not very great, and the unimportance of the harmonics compared with the fundamental rate of vibration in the current curve of the Ferranti machine renders the analysis of this current a severe test of the method, which, however, was sufficiently sensitive to show that the Ferranti current-wave consists of a fundamental rate of alternation, no appreciable components either for twice or three times the fundamental rate of alternation, but sensible components having respectively four and five times the rate of alternation of the fundamental; that is, the alternation is made up of a fundamental and the third and fourth harmonic.

Quite recently two of our students—Messrs. Healing and Le Tall—have been experimenting on another resonance method of analysing an alternate-current vibration which we have suggested to them, and, considering how rough is the apparatus they have been using, and how short a time they have been engaged on this new method, the results are unexpectedly satisfactory, and appear to show that this method, which is extremely simple, is one of great promise. The alternate current to be analysed is passed through a stretched wire, V V (Fig. 8), the length or tension of which can be varied as in a monochord. This wire is in a magnetic field produced by a permanent magnet, N S, or by an electromagnet, or, best of all, by a coil of wire surrounding the wire V V as a flat galvanometer coil surrounds the needle. As the current in the wire alternates the wire receives impulses backwards and forwards across the lines of force produced by the magnetic field, and if the length and tension of the wire be adjusted by trial until the natural time of vibration of the wire agrees with the periodic time of variation of the alternate-current, the wire oscillates vigorously with an amplitude from 1½ to 2in., emitting, of course, a musical note. The sudden way in which the wire starts vibrating when its length and tension are just right is very striking. The frequency can be determined from the musical note emitted by the wire; but as that would require tuning-forks or some other apparatus having fixed rates of vibration, as well as a musical ear, we prefer to determine the frequency by using the well-known formula for a vibrating string, viz.,

$$n=\frac{1}{2l}\sqrt{\frac{t}{m}},$$

where n is the frequency, l the length of the wire in centimetres, t the tension in dynes, and m the mass in grammes per centimetre of the wire.

In the first experiments we commenced with the wire comparatively slack, and on gradually tightening it up it was seen to vibrate very slowly. Holding one's finger on the wire and counting the vibrations, they were found to correspond with the speed of the engine driving the alternate-current dynamo D, which was sending the alternate-current through the wire. On tightening up the wire a little more it responded to twice this rate of vibration, which may, perhaps, have corresponded with the number of piston strokes; then the wire required a good deal of tightening, when it suddenly burst into vibration, and on calculating the value of n from the formula just given, a result was obtained closely agreeing with the electric frequency, which, with the particular dynamo employed was eight times the number of rotations of the armature per second. On tightening the wire still more, shriller notes were heard, and smaller waves seen superadded on the fundamental vibration of the wire as a whole. We were at first afraid that the analysis of the harmonics of the alternate current would be troubled by the vibrating wire having harmonics of its own, but we were reminded by Mr. Lamb of the well-known fact—which we ought to have remembered—that the harmonics possessed by the vibrating string of a musical instrument are impressed on it in the act of setting the string in vibration, or, in other words, that a string has no harmonics of its own. Hence we may safely conclude that the higher rates of vibration seen and heard with our wire are really due to harmonics in the alternate-current wave itself. To determine the frequency and amplitude of each of these harmonics the length and tension of the wire are adjusted until its natural period of vibration agrees with the particular harmonic sought for in the alternate-current, and which agreement is evidenced by the wire vibrating vigorously when it is attained.

We have not yet gone beyond this point in our experiments, but some modifications and developments of the method that have occurred to us may be briefly referred to. Instead of tuning the wire to accord successively with each of the harmonics sought for, it may be found convenient to have a number of wires tuned to give out, and therefore to respond to, different notes, as in a harp, and placed in a magnetic field, then to send the alternate-current to be analysed through them in parallel or in series (probably the latter would be better), and observe which of the wires vibrate, and what are the various amplitudes of vibration. Or, instead of sending the alternate-current through the stretched wire or wires, it may be sent round a solenoid or electro-magnet, and a direct current sent through the stretched wire or wires, placed relatively to the solenoid so that a current in the wire or wires is deflected by a current passing round the solenoid. Or, in place of a vibrating wire, a magnetic tongue the natural rate of vibration of which can be varied by altering its length or its moment of inertia, or in some other convenient way, may be placed near a solenoid or electro-magnet round which flows an alternate current. Or a set of such tongues tuned like the vibrating springs of a mouth-organ may be employed to analyse an alternate current sent round a solenoid or electro-magnet.

In the figure the alternate-current dynamo is shown near the vibrating wire, but it will be obvious that any one of these arrangements may be employed to measure the frequency of an alternate current at *any distance* from the dynamo. Or they may be used simply to measure the speed of the dynamo at any point of the circuit through which flows the alternate current produced by the dynamo if the number of alternations per revolution—which is, of course, a definite number for each dynamo—be known. Or, generally, if there be attached to any moving mechanism some arrangement for making and breaking a current, or varying the strength of a current, any one of these methods may be used at any distance from the moving mechanism to measure the frequency, and, therefore, the speed at which the mechanism is moving, so that the arrangement can be used as a simple speed-indicator for indicating at a distance the speed of moving machinery.

If the vibrating wire consist of two or more wires mechanically joined together, but electrically insulated from one another so that different currents can be passed through them, then, if the currents be of the same frequency, we can use our method for comparing the mean value of the algebraic sum of the currents with the mean value of any one of them; and by comparing the mean value thus found of the algebraic sum of two currents with what the mean value would be were there no difference in phase, we can determine this difference in phase. And the same thing may be done by sending the currents round different wires on a solenoid placed so as to cause a magnetic tongue to vibrate.

In fact, we have ourselves hardly yet realised all the uses to which this "electric frequency meter" can be put.

LEGAL INTELLIGENCE.

United Telephone Company v. Ahern and Company.

An action of the United Telephone Company (Limited) *v.* Ahern and Co., came before Justice Kay on Saturday, 29th ult., as a short cause, the defendants not having appeared.

Mr. MICKLEM appeared for the plaintiffs, and said the action was brought on two patents, the Edison and Bell, and the statement of claim stated that the validity of these two patents had come in question in a previous action, and had been established, and certificates granted. With the statement of claim had been delivered particulars of breaches, setting out the various acts of which the plaintiffs complained, and the order asked for was that the defendants might be restrained from manufacturing, selling, supplying, or using any of the telephone transmitters mentioned in the particulars of breaches, or any other instruments constructed according to the specification named.

Justice KAY said he could not grant the injunction in that form, the defendants not appearing. He did not think the particulars of breaches formed part of the pleadings, and, therefore, he could only grant an injunction restraining the defendants from infringing the patents mentioned in the statement of claim.

Mr. MICKLEM said the minutes further asked an order that the defendants do within seven days from service of the order deliver up on oath all infringing instruments in their possession or under their control, for an inquiry as to damages, and an order that the defendants pay such damages within 14 days after certificate, and all costs, charges and expenses as between solicitor and client, according to section 31 of the Patent Act of 1883.

His LORDSHIP made the order in this form

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

THE TELEPHONE COMPANIES' LICENSE.

For the better understanding of some of the points in dispute between the Telephone Companies and the Post Office we this week publish the chief clauses of the License under which the companies carry on their business. We do not know that the document has ever been made public before; but if it has, several of its leading features appear to have been forgotten by writers who have recently commented on the situation. As to the proposed amalgamation, clause 12 would seem to preclude that operation (supposing a transfer or assignment of *the powers or authorities* conferred by the License were contemplated) except with the sanction of the POSTMASTER-GENERAL. Probably this is not disputed; but it is argued that he ought to give his sanction because the amalgamation has been contemplated from the first, Clause 7 and sub-sections providing for such a contingency. That clause may be open to legal argument; but from a layman's point of view it strikes one as being—what the POSTMASTER-GENERAL has described it—a provision for enabling licensed companies to part with or acquire portions of other systems without rendering the vendors liable

Digitized by Google

for the royalty on the business disposed of. In other words, subdivision, not amalgamation, seems to be here contemplated. As to the bearings of Clause 12 on the actual circumstances we shall say something presently.

The preamble to the License contains a very explicit declaration as to the rights of the Post Office in the Telephone as a Telegraph, and to this proposition the signatories may be said to have assented once and for all. But besides this, there is a very noteworthy passage in Clause 19 which carefully guards against the assumption that in obtaining the concessions under the License the companies acquire any of the rights granted by Parliament to the Post Office. A perusal of this clause reveals one of the reasons which probably actuates the POSTMASTER-GENERAL in opposing the growth of a virtual monopoly in telephony similar to the actual and legal one possessed by the Post Office. It may be conjectured, however, that this is not his chief reason, which is a little more closely related to the pockets of the Treasury than to the convenience of the public. The question of State purchase has in fact—whether intentionally or not we do not pretend to say—been forced prominently forward by this project of amalgamation on the part of the United and its subsidiary Companies; and apparently the POSTMASTER-GENERAL is only awaiting a decisive expression of public opinion to determine his course of action next year. Several journals have frankly advocated a transfer of the whole Telephone service to Government control; others are ostensibly opposed to it, but apparently on no better grounds than that the Telegraphs have not prospered in Government hands! We reserve our own opinion for the present; but if no better argument than this can be brought against State purchase, the days of the Telephone Companies are numbered.

We have said that Clause 12 is explicit with regard to the assignment or sale of the powers or authorities conferred by the License. But the companies' contention, as we understand it, is that no such assignment is intended or necessary, the only operation involved in the present project being the transfer of business and plant, a transaction which the POSTMASTER-GENERAL has no authority to prevent under the License. In other words, the companies can assign and unite their businesses, although they may not assign their Licenses; and seeing that each of the companies possess a License covering the whole country, the License of any one of these companies will suffice, without meddling with any of the others, which presumably would be simply allowed to lapse. For example, with regard to the particular scheme now under consideration, a journal which claims to represent the Telephone Companies puts the case in a nutshell: "The License granted to the NATIONAL TELEPHONE COMPANY covers the whole country, and no legal sentence could prevent this Company from carrying on their business after having purchased the business of the two other Companies." It will now be understood why the UNITED COMPANY in its letter to the Post Office of 14th June argued the point exclusively on the right of a Joint Stock Company to transfer its business as it may deem fit, and made no reference to the Post Office License which, from the Company's point of view, reserves only the right to prevent the assignment of those "powers or authorities" which are granted by the Post Office.

And we can now also appreciate the POSTMASTER-GENERAL'S hesitation in pronouncing a legal opinion on the interpretation of the clause. Unless there exists some other condition which we have overlooked outside of Clause 12, it seems to us that there is nothing in it to prevent the National Company doing what they propose to do, and that they will only be deterred from doing it by the covert threat of the POSTMASTER-GENERAL to avail himself of the purchase clause (17) next year. Of course the point is a technical one on both sides, and we suppose that the companies will not deny that they are straining it to its utmost, as indeed they have a right to do. On the side of the Post Office it will now be seen that in guarding against one danger at the outset they have incurred another of greater magnitude later on. If the licenses had covered only certain limited and defined areas, obviously the licensees could not have united unless with the POSTMASTER-GENERAL'S consent; but seeing that the powers of the licenses are not so restricted, any one of the licensees can absorb the whole country's business without consulting him. The upshot is somewhat startling, and is plainly not what the Post Office intended; but the case thus presented by the companies is a very plausible one, and unless Mr. RAIKES has some counterblast in reserve he will have to either allow the amalgamation to proceed without further unavailing protest, or take into serious consideration the invitation of the journal already quoted, and "buy up the telephone companies next year." At the meetings of the two principal companies held yesterday the resolutions authorising the amalgamation were fully confirmed. As will be seen by our Parliamentary intelligence, the subject occupied the attention of the House of Lords last night.

PROBLEMS IN ELECTRIC TRACTION.*

BY DR. LOUIS BELL.

The preliminary stage of electric tramways is to-day quite gone by. While three years ago such an application of electricity was regarded very dubiously, that doubt is now displaced by the certainty that the electric road is a success and has come to stay. The live question to-day does not involve the chances of the electric road but the chances of its competitors. There are now something like fifty electric roads in regular daily operation in the United States, covering about two hundred miles of track, employing all sorts of systems, working under all manner of adverse conditions, climbing grades of pitch equivalent to four and five hundred feet to the mile, taking curves of all possible radii, and there has been with all this no report of failure anywhere. On very many of these roads electricity has replaced horses, and nearly every week brings reports of similar substitutions elsewhere. No inroads have as yet been made on the cable systems, but it is an open question whether they can hold their own, even in the favourable localities where they are already established. No one need ask, in face of these facts, whether electric traction is practicable or successful, but rather such questions as these: How efficient is it? What is its first cost, compared with horse or cable traction? How do its running expenses and repairs compare with these? What grades and curves can safely and economically be taken? What accidents is it liable to, and how can they be prevented? What are the conditions of efficient and economical running?

It was for the purpose of attempting to answer some of these vital questions that the present investigation has been carried on. To obtain thoroughly practical results applicable to the everyday working of an electric tramway I have not concerned myself with theoretical motor tests and curves, but have confined myself quite closely to actual car tests of power and efficiency and to the evidence of the ammeter and the indicator diagram at the power station. The man who contemplates putting his money into an electric road does not particularly care about the characteristic of the motor used, but he does want to know how much power must be developed on his cars, how much coal he must burn at the power station to obtain it, what efficiency he may expect from the system, what are its weak points, and how they may be strengthened.

Through the kindness of Mr. Hawter, superintendent of the La Fayette (Ind.) Street Railway, every facility has been afforded me for making a thorough and detailed test of the road, and such of the results as may properly be published are recorded in this paper, only such details as directly concern the private business of the company being omitted.

Before taking up or discussing these experimental results, I purpose considering the general conditions under which electric roads must operate, the general difficulties to be met with, and the relations of this method of rapid transit to those with which it has to compete. There are many requirements for street railway work which are not met with in any other kind of traction. For

* From the *Electrical World* of New York.

Digitized by Google

most of these the electric motor is admirably adapted, while for a few it is not. Consider, then, the conditions to be met in street railway work and the properties that a motor of any kind must have to be thoroughly suited to these conditions.

1. To meet public convenience a tramway line must in nearly every case run through the most frequented business streets of a town, and outside the business portion must pass through, or very near to, the thickly populated residence streets and on to the larger suburbs. It, therefore, is generally not at liberty to pick out a route of the easiest grades and curves, but must be able to surmount quite severe grades readily, and take without much danger of derailment any curves that the streets require, sometimes of radii barely above twenty feet.

2. It should be thoroughly reliable, *i.e*, track and motor system should be so constructed that the system will be of very little danger, first, of a complete breakdown, interrupting travel throughout the line, and second, of local accidents sufficient to pile up cars at any particular point.

3. It should have a considerable flexibility in the matter of speed. In any line where the cars run on anything like a fixed schedule, as will always be the case in anything except the very largest lines, they must be able to make up lost time within reasonable limits in case of a trifling accident or unusually frequent stops. For this reason the maximum speed should be considerable.

4. It must be able to stop and start quickly and easily. Running through crowded streets and liable at any moment to find its tracks blocked, the only security against serious and frequent accident is in the ability to stop quickly, even when running at full speed. Easy and quick starting too is quite necessary, since so much of the running time is taken up in just this way.

5. Track and motor system should be of such a kind as will cause the minimum amount of obstruction to the streets and annoyance to the travelling public. For this reason the rails are very low and unobtrusive, consequently somewhat less secure. Since most of the traffic is and will continue to be carried on by means of horses, any system that renders it difficult or dangerous to drive in the same street is open to objection.

6. The motor system should be tolerably silent, and of such a kind as not to prove a nuisance to the streets through which it passes.

7. It must be so arranged as to meet readily the demands of an unusual crowd at some one point. It frequently happens that most of the cars of a system must be started under nearly full load within a few minutes. This is specially true of lines connecting with suburbs, where the traffic is likely to be very uneven.

With all this, any tramway system must be tolerably economical in operation, and its first cost must not be prohibitive.

These conditions cover most of the points in street railway work, although in special cases they may be considerably modified. To meet these requirements all sorts of devices have been brought out. Taking, then, the three systems in extensive use, viz., cable, horses, and electric traction, let us see wherein they do, or do not fulfil, the above conditions, specially seeking out the weak points and difficulties of the electric systems.

So far as grades are concerned, the cable system easily takes first rank, for its power of hill climbing is limited only by the power of the grip and the tensile strength of the cable. Of course such excessive grades are neither desirable nor economical, but now and then they are almost unavoidable. Sharp curves can, of course, be employed on a cable system, but with disastrous effect on the life of the cable and the efficiency of the system. The wear and tear on a cable with many curves is very severe.

With horses very steep grades are exceedingly objectionable, but by the aid of hill horses can be taken, except in slippery weather. At best horses are far inferior to the cable system for grade work, though a horse car can safely take a curve that nothing else can, for the horses tend to guide and pull around the head of the car while in any motor system there is a certain tendency to jump the track even in spite of guard rails.

With electric roads the case is quite different. The motor cars depend on adhesion alone for hill climbing, and beyond a certain point adhesion fails. In such a car, however, the whole weight of car and contents rests directly upon the driving wheels in most cases, and consequently theoretically the possible grade per cent. should be numerically equal to the coefficient of adhesion. This can hardly be estimated exactly except by experiment in a given case, and street car tracks are generally not carefully enough laid to give good results. The data obtainable, however, would assign something like 20 per cent. as the maximum practicable grade and the real limit probably lies below this. As to the evidence offered by actual experience under working conditions, it is certain that with proper care of the track grades as high as 400 feet per mile can be operated with entire success. This presupposes that the rails are kept in good order and clear of sleet and snow. With extra vigilance in this respect, aided now and then by a little sand, I think it would be feasible to take grades of 500 feet per mile if necessary. Above a 10 per cent. grade the case is rather precarious when we consider the effect of rough weather. Occasional grades of greater pitch may be taken if they are not too long and conditions are favourable. As to curves, the electric roads are practically unlimited, but curves on grade are particularly undesirable and in any case the speed should be reduced and the track well supplied with guard rails. Save on a steep grade there is no likelihood of trouble.

As regards reliability, one may divide the various systems into two general classes—those in which each car is an independent unit, and those where all the cars have a common source of power. The former class comprises horses and the electrical accumulator system; the latter, cables, and all other modifications of electric traction. All traction systems are liable to occasional local mishaps, but a general breakdown is very improbable in the first class, while in the second it is likely now and then to occur.

With the usual electrical systems a general stoppage, except in very rare cases, is due to a single cause, a serious short circuit at some point on the line. The wiring is usually arranged so that a broken wire, aside from the contact wire, causes no serious trouble, and even if the contact wire breaks, only a short section of track is thrown out of service. If a bad short circuit occurs, however, it may become necessary to shut down the entire line. But such an accident can be remedied almost as soon as the scene of it can be reached, and a broken wire is very easily mended. Electrical roads are, however, quite liable to minor accidents to single cars. Brushes will turn, trolleys will come off, gears will occasionally break, field coils will now and then burn out and local short circuits occur. Most of these mishaps can be soon remedied, and not a few of them averted by a vigilant system of car and line inspection. In fact, I think it would be quite safe to say that three-fourths of these local accidents can and should be prevented.

Great power of varying speed is one of the characteristic advantages of the electrical systems. The speed may range from four or five, to fifteen miles per hour at will, each car being separately driven and controlled. As the ordinary running speed is considerably below the maximum, trains can be made up quite readily, and the speed lowered very much in crowded streets without resorting to stops and starts. Horse cars possess something of the same flexibility, but their maximum speed is so low that with modern needs for rapid transit the horse car must eventually disappear. As is well known, cable roads work virtually at a fixed maximum speed and can only slow down by letting go the cable.

The same qualities that give an electric car a widely varying range of speed give it also the power of starting very smoothly and easily. In this respect it is decidedly superior to the cable cars, which, although they can be made to start with tolerable ease, usually do not. In addition, the electric car possesses an almost unique power of stopping suddenly in case of need. In a crowded street, it not infrequently happens that man or beast slips directly in front of a moving car. With horses or cable, many accidents have resulted. With the electric car, however, the cases would be exceedingly rare in which a prompt reversal of the motors would not avert such a result, for if there is need, an electric car at full speed may be stopped within its length. I have seen a horse fall on the track within a few feet of a car at ordinary speed, and the car brought to a standstill without touching him. A man has been knocked down by the dashboard and the car stopped before the wheels reached him. Of course such sudden stoppage is only attempted in case of dire necessity, but when that necessity comes it can be and is done.

So far as track is concerned, all tramway systems have about the same requirements. In the case of all motor cars of whatever kind there is more or less trouble from frightening horses, and, for a time at least, making the streets dangerous to drive upon. Every place in which a motor system has been started can show a record of a rather serious kind. It is certainly an important consideration. Horses, however, soon become used to motors, and the main difficulty is only temporary. But all overhead electric systems and all using the rail as a part of the circuit are especially likely to scare horses on account of the frequent flashes from trolley or rails, or blazing at the brushes.

As regards noise, electric and cable cars are at present not widely different. In the electric systems the incessant grinding of the cable all along the line is absent, but the noise of the gearing is often considerable, particularly after it becomes worn. At present gearing seems the most feasible method of reducing the speed of the motors, but except when new, it is far from silent. The noise, however, of either cable or electric cars is not so great as to constitute a valid objection to their use.

With a proper plant, any of the electric systems can handle traffic massed at one point in a way that leaves little to be desired.

Aside from the general conditions to be met, an electric road encounters certain difficulties quite peculiar to itself, some of

Digitized by Google

them real, others rather to be classed as imaginary. In the first place there is a widespread popular delusion that the overhead wire in general use is exceedingly deadly, and that the track used as return circuit is scarcely less so. As a matter of fact, the maximum potential used in tramway work, 400-500 volts, cannot be classed as even dangerous. It would, of course, be decidedly unpleasant to receive the full effect, but there is no reason to believe that it would imperil life, or cause a more serious injury than burns at the point of contact. In fact, a large number of *employés* of electric roads have received the full E.M.F. without injury. In addition the wire is carried so far out of reach that the public cannot get at it, and even if it falls it is soon got out of the way. The track return is perfectly harmless. These facts are well known wherever an electric road has been in operation for any length of time.

It is, nevertheless, quite clear that the overhead system must be abandoned in large cities, except in some few special cases. Eventually all wires must and will go underground in such situations, and electric tramways, like electric lighting systems, must face the difficulty. That this difficulty is a real one no one who has watched the progress of underground work will care to deny, but the ostentatious collapse of certain electricians under the weight of the problem is hardly in keeping with the skill and readiness they have heretofore displayed. Fortunately the case for tramways can be easily solved, either by a conduit or storage batteries. Which of the two will furnish the ultimate solution of the problem depends mainly on the progress made in accumulators within the next few years. Could the accumulator be reduced to a reasonable weight, it would certainly furnish the ideal method of electric traction.

There is one question, however, that is of great and growing seriousness in electric traction, and that is the interference of an electric tramway of the ordinary type with the telephone lines in the vicinity. First, there is the danger of a cross circuit between their respective wires where the damage will be all on one side; and second, the fact that an electric tramway using ground connections may quite paralyse all the telephone circuits in the immediate vicinity. The first danger may be in great measure avoided by a proper system of guard wires, but the second difficulty is of no small moment, and cannot so easily be met. The effect of a traction line on all neighbouring telephone lines is very marked, in some cases rendering them almost useless. The exact nature of the phenomena produced is very complicated. Listening at a telephone thus affected, it is possible to follow in considerable detail the operation of the motors. Whenever a car is started, a low hum is heard, gradually rising in intensity and pitch as the speed increases, and as the connections are shifted from step to step on the switch-box. Beneath this distinct note is a confused whirring sound of lower pitch and greater intensity. The effects are clearly due to the super-position of several different periodic variations in the current and electromotive force on the traction line. The transference of this disturbance to the telephone line depends on two quite distinct causes; first, the direct effect of induction, and second, the disturbance due to the fact that both systems are grounded at points not very far distant from each other. The relative importance of these two causes varies very widely in different places. Here most of the trouble comes from direct induction, while it is not uncommon to find nearly all of it coming from the grounds. Both causes must in general be eliminated to avoid the difficulty.

Examine first the cause of the fluctuations which produce induction. Any motor the armature of which is wound in a finite number of sections must, in the first place, produce sinusoidal variations in the motor electromotive force. These, however, are of small amplitude, less than one-half per cent. in motors generally used, and are in this case of minor importance. Their period corresponds to N n per second, where N is the number of revolutions per second and n the number of segments in the commutator.

Besides this there is a periodic variation of the ohmic resistance of a motor due to the fact that the brush in sliding from segment to segment momentarily short circuits the ends of an armature coil. Let n be the number of armature sections and r the resistance of each, R_1 the resistance of the armature from brush to brush, and R_2 the resistance of the series field coils. Let the motor be supplied, as is usual, in practice at a constant electromotive force. Then, assuming the brushes to be 180 degrees apart and touching one segment the resistance of the motor is—

$$R = \frac{n r}{4} + R_2.$$

Now, revolve the armature until each brush touches two segments, and—

$$R = \frac{(n-2)r}{4} + R_2.$$

Therefore when the motor is running at a constant speed the current will be subject to fluctuations of amplitude determined by the above, and occurring n N times per second. Take, for example, the ordinary Sprague motor where $n=24$, $R_1=1{\cdot}2$, $R_2=3{\cdot}3$ (last step) $r={\cdot}2$, the amplitude of the fluctuation is somewhat over 2 per cent. of the normal current. As the cars are fitted with two motors in parallel, if the two sets of brushes short circuit simultaneously we should have a double effect and a variation of 2 per cent. in the total current through the car. If they do not short circuit simultaneously, a variation of half the amount 2 n N times per second.

Another small periodic disturbance is due to the fact that the brushes are very generally unsymmetrically placed, with the result that the motor electromotive force in the halves of the armature will be slightly unequal The result is as if a weak alternating current were acting in the armature with 2 N n alternations per second.

Another and more serious difficulty occurs when the insulation between the commutator segments is somewhere near the width of the contact edge of the brush. In this case there would be produced a fluctuation which might almost amount to a make and break, and would have N periods per second if the brushes were symmetrical, and 2 N if they were not. The fluctuations due to this cause are frequently considerable. Add to this the possible irregularities in the commutator contact, and we have a combination of sinuous and alternating disturbances of an immensely complicated kind.

Of course, the remedy for induction is well known—giving the offending current a return wire, so placed as to neutralise its effect, or adopting a simlar process, with the line disturbed. The case of earth disturbances has recently been investigated by Mr. Preece (*The Electrician*, Vol. XXII., p. 618.) His results show that the effect of a grounded sinusoidal current may extend to a great distance and may cause very much worse disturbance on a telephone line than simple induction. These facts would suggest that in all electric traction work a complete metallic circuit should be used, and that grounding *viâ* the rails should be avoided. Double contact wires, however, are certainly objectionable where they have to be supported by a system of wires, both as being somewhat troublesome mechanically and as being unsightly. Unless guarded with great care they will much increase the danger of troublesome short circuits. Where, however, they can be supported on brackets, and hence more efficiently guarded, their use should furnish an effective way out of the telephone difficulty. But in very many cases it is desirable to use the single overhead wire, and some simple means of avoiding at once earth and induction is desirable. Clearly it is not sufficient to use the track alone for a return or the track with an auxiliary wire beside it, as is quite usual. For the current of supply is, or always should be, divided between the trolley wire and a line wire connected with it at intervals; hence the inductive effect of this overhead system can never be balanced by an equal current along the ground by reason of unequal distance from the overhead telephone wires. I would therefore suggest the following as perhaps the simplest and easiest way of abolishing the induction:—Connect the rails so as to form a return circuit leading either back to dynamo or to a main earth at some unobjectionable point. Then remove the auxiliary wire from the track to form a second return circuit parallel to the line and nearer than it to the telephone lines. Finally connect these two return systems at any convenient number of points by wires under the surface and up the nearest pole. Neither track nor these cross wires need be carefully insulated. The supply current then is divided between line and trolley wire and the return between auxiliary line and track. The most of the former current would pass along the line wire and most of the latter along the track. Since the coefficients of self-induction will be quite nearly equal, the disturbing fluctuations will divide in the same ratio as the currents, and we have a system of four conductors in which the two fixed ones, trolley wire and track, nearly neutralise each other, the larger current being the more distant from any overhead wires; while the two movable factors, the two-line wires, can be so arranged as to complete the compensation. Given the resistances, such a system can be easily arranged, so that the resultant induction on any single wire would be *nil*, and remain very small throughout any compact system of wires. It would be practically very difficult to secure compensation with fewer conductors than four so long as two of them must be approximately fixed. This four-conductor system could be applied to existing lines with small trouble and expense.

I will now pass to the efficiency tests made on the electric road in this city. The Lafayette Street Railway Company operates 3·6 miles of single track on the Sprague system. The line was operated by horses until the summer of 1888, and has now been operated as an electric road about eight months. The track is a branching one, extending on both sides of the Wabash River and reaching well out to the city limits. The grades are in some places severe. In the central part of the city which lies in the old river bottom the grade is very light, but on the east side the road rises sharply, taking at first a slight grade and then one of about 6·6 per cent. and fully 800 feet long, averaging 7·34 per cent. for 100 feet in one section. On the west bank of the Wabash the road rises over the bluff, taking a 6 per cent. grade for about another 800 feet, with a very sharp

Digitized by Google

curve near the middle point. There are more than a dozen curves in the road, most of them of a rather short radius. There are seven motor cars, of which six are in continuous use. The cars are closed, weigh complete about 5,200 pounds, seating 20 persons readily, and holding at a pinch between forty and fifty. The plant combines a plant for stationary motors with that for the street cars. There are two of the regular Edison railroad dynamos coupled in parallel, each having a normal capacity of about 30,000 watts at 500 volts, or rather more in case of need. Two other Edison dynamos of about half the capacity supply the power circuit at a potential of about 250 volts. Power is supplied by a Hamilton-Corliss engine, 14in. by 36in., running at 88 revolutions per minute. Two large horizontal tubular boilers furnish steam at a normal pressure of 85 pounds, and have a large margin of capacity. The two railroad dynamos and one of the power dynamos are used continuously, the former 16 hours, the latter 10 or 12 hours per day. The first car leaves the end of the road at 6:20 a.m., and the last car gets in at 10:20 p.m. Each car makes from 35 to 40 miles per day, is operated by a single man, and can, if necessary, take one of the spare cars in tow to accommodate an unusual crowd.

The first tests were made at the power station, with the object of determining the actual electrical output on the road, the indicated horse-power necessary to produce it, and the amount of coal required. To this end the engine was indicated every five minutes throughout the day, beginning and ending this series with a group of friction cards. Meanwhile the electrical output was simultaneously obtained from volt and ampere readings. The volts were read on an Ayrton and Perry voltmeter, and the amperes on the station ammeter, which was afterward checked as well as practicable by a new Ayrton and Perry ammeter. The coal burned during the test was measured and its weight determined.

The results of the friction cards were as follows:—Friction of engine + 3 dynamos average: morning, 12·5 indicated horse-power; night, 19·1 indicated horse-power. A number of cards taken on different days gave almost exactly 16 indicated horse-power, which we may take as a fair average for the power wasted in friction. The dynamos are all belted to a main shaft which is driven by a belt from the engine. This shaft is well in line and kept in good order. In fact,

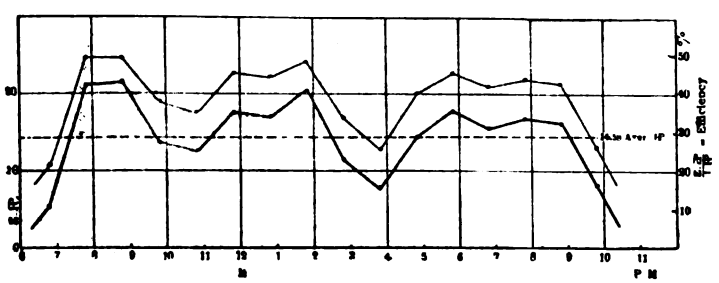

FIG. 1.—Variation of Electrical Horse-power and Efficiency, Lafayette, Ind., Electric Railway.

the station is a model of neatness and the machinery is looked after with unusual care. These figures give for the approximate friction of the engine alone 12—14 indicated horse-power. In other words, we may take the engine friction as 10 per cent. of its rated full power.

The five-minute indicator cards were worked up very carefully, and gave as the average continuous power throughout the day 39·05 indicated horse-power. The highest figure reached was 79·3 indicated horse-power, and from this figure the power fell to the friction cards as a minimum.

In a similar way the readings of volts and amperes were combined and showed an average that was remarkably low, being 10,881 watts, equal 14·58 estimated horse-power. The greatest output recorded was 90 amperes, 410 volts, 36,900 watts, equal 49·46 estimated horse-power. This figure was reached only for a few seconds. This is not as great an output as is sometimes observed on the line, where occasionally 75 estimated horse-power may be demanded, though such a call for power is quite unnecessary under ordinary working conditions. The ammeter readings not infrequently fell to zero for a few seconds at a time. To obtain the total electrical horse-power for comparison with the indicated horse-power, we must add to the above the amount obtained by a similar approximate integration of the power used on the stationary motor line, which was 1·25 estimated horse-power. The amperes on the car line varied from 0 to 90, and the volts from 405 to 480, averaging about 450. A sudden call for a large current invariably lowered the potential to about 410, and tended to slow the engine momentarily, for the governor only began to act some two seconds after the current rose; and so sudden are the variations in current that nothing short of compound winding can possibly keep the dynamo at anything like constant potential. The electrical output varied greatly during the different hours of the day. Fig. 1 gives this variation of the output with the time in a very marked way. The heavy line gives the estimated horse-power required hour by hour. The variation is very large, and causes a similar variation in the efficiency of the power-station, since the main losses are nearly independent of the output. Combining now the indicated horse-power at the engine with the estimated horse-power on the car line, and making proper allowance for the power consumed in the lamps and on the stationary motor line, we have as the average efficiency of the power station, $\frac{\text{E.H.P.}}{\text{I.H.P.}} =$ 40·7 per cent. average throughout the day, and for the maximum efficiency, $\frac{\text{E.H.P.}}{\text{I.H.P.}} = 65·0$ per cent. The light line in Fig. 1 gives the variation of the efficiency throughout the day.

The coal burned during the day was 4,500lb. of slack, which is at the rate of 7·31b. per indicated horse-power hour, or nearly 16lb. per estimated horse-power hour. We have shown in these facts by far the greatest source of loss in electric traction, both here and elsewhere. It is worth while considering in some detail the nature and cause of this loss, in how far loss at this point is necessary, and what means can best be taken to lessen it. The key to the whole situation lies in the immensely irregular calls for power in a tramway system. The cause of this irregularity is obvious; the annexed diagram (Fig. 2) will give a feeble idea of its amount. It shows the variation of the current on the line as given by the five-

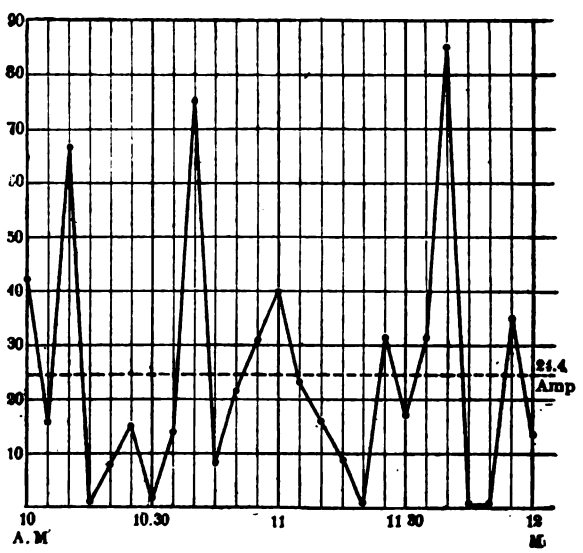

FIG. 2.—Variation of Current, Lafayette, Ind., Electric Railway.

minute readings between the hours of ten and noon on one of the days of test. Comment is unnecessary. But even this does not represent the real amount, for as a matter of fact the current is never even approximately constant for more than a few seconds at a time, and varies from *nil* to 60 or 70 amperes in a way that nothing but a continuous record can show. As a result of this, the mean output is, on a system of this size, less than 25 per cent. of the maximum, which may be called for and must be furnished at any moment. As the system becomes larger the ratio of mean to maximum output increases, until for a large system it may amount to one-half. The value of this ratio on the Richmond (Va.) road, judging from Mr. Sprague's figures, rises to nearly this amount. The values will then range from ·2 for a small road with high grades to ·5 or ·6 to a large road (40 or 50 cars) in a level region. Grades evidently tend to diminish its value considerably, though their effect may be partially counteracted in a small road by tact in arranging the schedule. To supply power to such a system an engine must be able to give the maximum power demanded on very short notice, and will be habitually worked at from a fifth to a half of its full horse-power. This affects the efficiency of the system in two very pernicious ways, first by requiring the use of a disproportionately large engine with friction to match, and second, by working that engine in a very uneconomical way. As regards the first count, the friction of an engine is nearly independent of the load, quite as often decreasing under heavy load as increasing. It gradually increases with the speed, and slightly increases with increasing length of cut-off. As to the amount of friction, it varies, of course, very widely, but in modern engines of good make it will generally be from 5 to 10 per cent. of the full normal output. This means, then, that if such an engine be worked on the average at a quarter of its full power the loss from

Digitized by Google

friction will be from 20 to 40 per cent. of the indicated horse-power, usually much nearer the latter figure than the former. This is bad enough, but it is not the worst. When used under these circumstances, an engine is on the average working under conditions of expansion very far from economical. The cut-off is very much too short for advantageous working. The best point of cut-off is probably given by Emery's formula—

$$\frac{1}{r} = \frac{1}{1+\frac{p}{22}},$$

where r is the ratio of expansion and p the absolute pressure in pounds per square inch. Even this point of cut-off is probably rather small for ordinary engines. Applying the above formula to the case of the engine tested in these experiments, the best point would appear to be between one-fourth and one-fifth stroke. On examining the indicator cards taken at or near the point of average output, the engine seems to be cutting off at between an eighth and a ninth of the stroke. There is, therefore, a disastrous amount of condensation, and the final result appears in the 7·3 pounds of coal per indicated horse-power hour. A Corliss engine like the one in question should, if used under favourable conditions, give the indicated horse-power hour for three pounds of coal or less, while under this erratically varying cut-off it requires more than twice that amount. It is very important then to avoid as far as possible these very wasteful conditions of working. The problem then is to work an engine on the average at its most economical point of cut-off, while retaining the power of responding to sudden, though brief, demands for several times the average horse-power. In the first place, these sudden demands are sometimes but for a second or two, generally for less than half a minute, and whatever the engine used, a heavy fly-wheel would be of great service in smoothing the irregularities of the output and helping the engine through a sudden emergency. Second, the engine itself should have a very wide range of cut-off to enable one to make the average expansion the most economical one. In an engine which must be habitually used at one-fourth power, the steam should be made to follow for nearly full stroke if necessary, in order to bring the average point of cut-off to the right value. Any valve gear which cannot cut off beyond half stroke is decidedly objectionable, since it necessitates too large an engine and too great a ratio of expansion. To avoid friction as well, the engine should be the smallest, competent to furnish the maximum power; hence it should take high-pressure steam and have a high rotational velocity. As regards application of power, it should be as direct as possible, avoiding countershafts and the like. All these considerations point distinctly to the use of high-pressure steam in a rather small high-speed engine capable of cutting off up to three-quarters stroke, driving a heavy fly-wheel, and belted direct to the dynamos. Such engines can be obtained and are capable of giving the indicated horse-power hour on 3—4lbs. of coal. The day of low speeds and gigantic cylinders is fast passing by, and nowhere do they appear at less advantage than in work under extreme variations of load. An engine of the kind mentioned above would, under favourable conditions, have a coefficient of friction not exceeding 15 per cent. of the average indicated horse-power, and require less than 5lb. of coal per indicated horse-power hour, even under the variable load necessary. It should then be able, when belted direct to the dynamo, to give the electrical horse-power hour for about 7lb. of coal. The load being less variable in a large power station, conditions of economy are more easily reached, and as nearly as can be calculated from Mr. Sprague's data in the power station of the Richmond, Va., road, the estimated horse-power hour required about 9lb. of coal. As to the amount of power actually needed to operate a tramway line, the tests made here show almost exactly 2·5 estimated horse-power per car. This is a smaller value than would be obtained from a larger and more heavily-loaded line. The diagrams given by Mr. Sprague show that on the Richmond line the power required was approximately four to five estimated horse-power per car. The Richmond cars, however, are larger and heavier than those here. In general, the power required seems to be 3—5 estimated horse-power per car. To furnish this output the engine should be capable of producing about 10 to 15 indicated horse-power per car at full (say $\frac{2}{3}$) cut-off, the former figure for large and level systems, the latter for small systems and those with excessive grades. It should then be practicable to bring the efficiency of the power station, $\frac{\text{I.H.P.}}{\text{E.H.P.}}$, up to 70 per cent., in lieu of the 40 per cent. observed in these experiments. The efficiency of the Richmond system, which is operated by Armington and Sims' engines running at 250 revolutions per minute, must be somewhere near this figure, certainly as high as 60 per cent. This efficiency, it should be remembered, is not secured at any great expense, for such a plant is quite economical in first cost as well as in operation.

(To be continued.)

THE PHYSICAL SOCIETY.

The last meeting of the Society for the present session was held on the 22nd inst., Mr. A. W. Clayden read a note on

"Some Photographs of Lightning and of Black Electric Sparks."

The author exposed several plates during the thunderstorm on June 6, and three of these gave results.

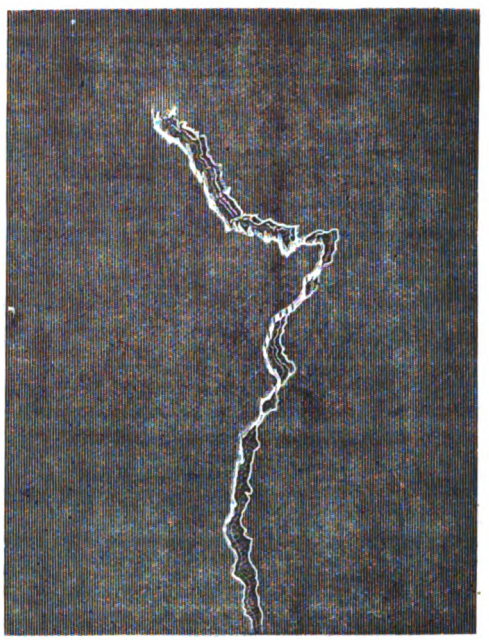

FIG. 1.

Two of the flashes of which photographs were obtained, exhibited complicated and beautiful structure.

They are shown in Figs. 1 and 2, which are taken from an enlargement of the original photograph.

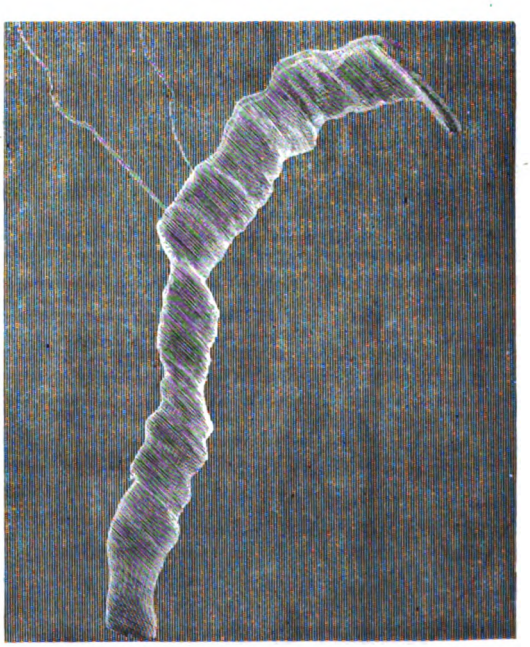

FIG. 2.

One of these is a multiple flash, the enlargement of which shows a curious flame-like appendage pointing upwards from every angle, while the other is a broad ribbon. Some masonry came into the field of view of the photograph, and this came out quite sharply in the negative, showing that no perceptible motion of the camera occurred during the existence of either flash. Another of the plates gave some very interesting results. During the exposure of the plate the author had noticed about six flashes which appeared likely

Digitized by Google

to come within the field of view, especially one, which passed right across the centre of the field. On developing the plate, however, nothing was seen at first but one triple flash in the corner.

The plate was very much over-exposed, and the image required careful nursing. When the plate was carefully examined, however, the image of the vertical flash specially noted was discovered, together with several others, but they were all dark flashes. The enlarged plate showed indications of a white core to each of them.

The connection between this reversal and over exposure suggested to the author that the black images of the flashes might be due, not to the excessive brightness of the flashes, but rather to the cumulative effect of the glare from the illuminated white clouds forming the background. To put this idea to the test the author endeavoured to obtain similar effects with the sparks from a small Wimshurst machine giving sparks about an inch in length. He

FIG 3.—Bright sparks, different parts of the plate being exposed to diffused light for from 1 to 6 seconds respectively.

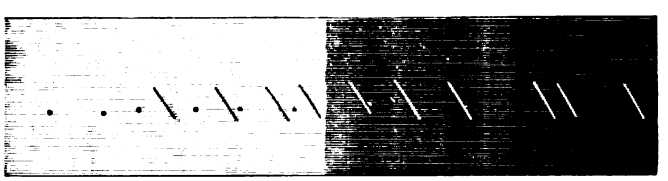

FIG 4.—Left-hand portion exposed to diffused light for 1 second.

FIG. 5.—Series of sparks with background of white cardboard.

first photographed a series of brilliant sparks obtained by including two large Leyden jars in the circuit. The results of these photographs were of a normal character, except that they shaded off at the margin in spite of the focus being good, as shown by the distinct image of the knobs of the machine. Photographs were then taken of the less brilliant sparks obtained when only the ordinary small jars were included in the circuit. The images were similar, but less dense. Both experiments were then repeated, but before developing, the plate was exposed to diffused light from a gas-flame. The fainter sparks were then completely reversed, while the bright ones were reversed at the edges, but had bright cores. Fig. 3 shows the result of exposing different parts of the plate for one, two, three, four, and six seconds respectively.

Fig. 4 shows the result of exposing half of a plate containing images of faint sparks to diffused light for one second before developing.

Fig. 5 shows the result of photographing a number of sparks in a series across the plate, with a background of white cardboard representing the white background of cloud in the photographs of lightning flashes.

Two of these sparks, viz., those marked 1, 1, in the figure show reversed images. They were among the first impressed upon the plate.

DISCUSSION

In the course of the discussion which followed, Mr. W. N. SHAW exhibited a photograph (Fig. 6) taken by his friend, the Rev. A. Rose, during the

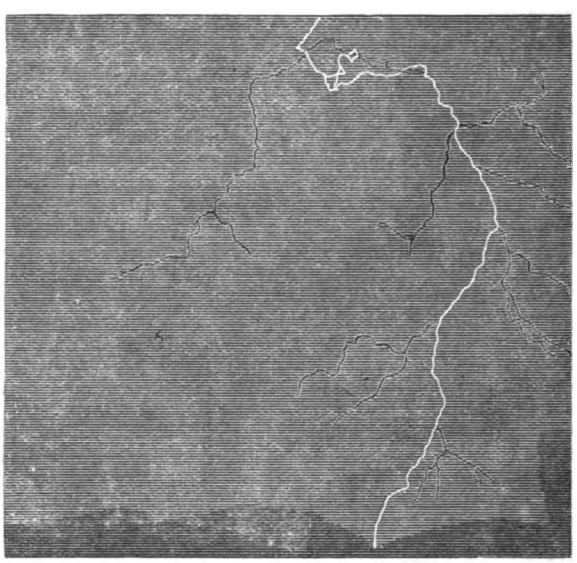

FIG. 6.

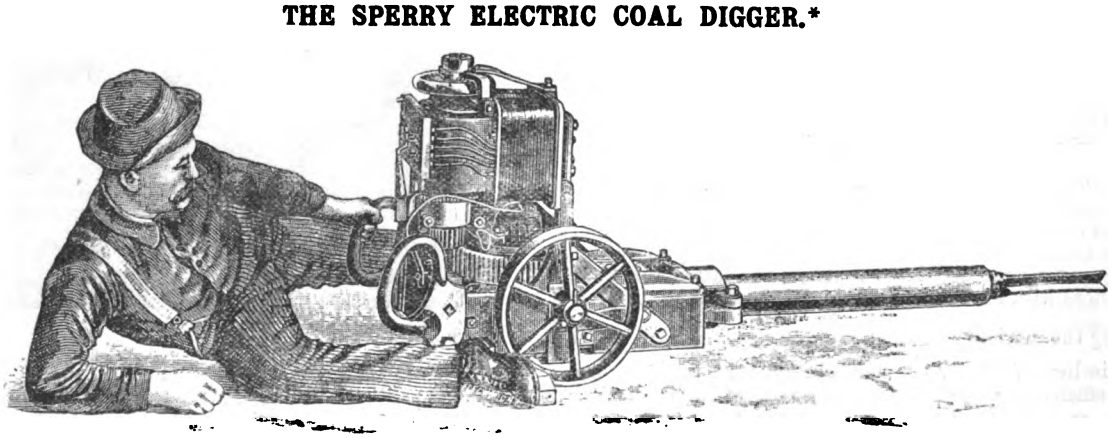
recent storm, which showed bright main flashes with dark flashes branching from it. He thought that the dark flashes could not be due to over exposure, as in this case the central part would be the most exposed. One of the side flashes showed a white line along its centre, which appeared to confirm Mr. Clayden's opinion that the reversing effect proceeded from without inwards.

Prof. PERRY thought that this photograph confirmed Mr. Clayden's theory, as the side flashes were not so bright as the central one.

Mr. CLAYDEN, in replying to the discussion, observed that the diffused light appeared in some manner to undo the photographic effect of the spark or flash. He did not think that Prof. Stoke's theory that the reversal was due to the absorbtive effect of gases produced by a preceding discharge along the same path could explain the existence of the unreversed core.

THE SPERRY ELECTRIC COAL DIGGER.*



At the last meeting of the National Electric Light Association, held in Chicago, the new Sperry Electric Mining Machine was exhibited for the first time. This machine has since been sent to the Paris Exposition, where it will be exhibited in operation. The machine is the latest of Mr. Sperry's many inventions. He was encouraged in perfecting it by Mr. A. L. Sweet, one of Chicago's most prominent coal men, who has in past years spent considerable money with other inventors in this line, but without practical result.

* From the *Electrical World* of New York.

Digitized by Google

Though this machine was the first made, and naturally liable to some faults in construction, the results reached in actual work in the mines gave promise of a good future performance, which has since been verified by the second machine, which is illustrated below, and which gave the following results :—

Number of tons undercut, one man and one helper, 10 hours, 6ft. vein	110 tons.
Depth undercut	4ft.
Length of face	120ft.
Horse-power required on surface	2·55
Cost of wires per running foot	$0·02
Distance from power to face	1,600 ft.
Number of blows per minute	200 to 250

The machine has been handled by a number of miners experienced with mining machines. They are loud in its praise and pronounce it the easiest machine to run they ever held, that it is almost entirely free from *recoil* and that each blow can be put in exactly where it is wanted. One great advantage and a unique feature is that no matter at what point in the stroke the pick is arrested by the work or face it is returned from that point instantly for the next blow and does not stand and push the miner back. Both the time and the power which would go into the remainder of the stroke are saved. This most important result is accomplished in the following manner :—

A crank operates by means of a pitman to draw back or compress an extremely powerful spring. The crank is not attached rigidly to the power shaft, but is so arranged as to be automatically engaged with the power shaft only when the strain upon the crank is in opposition to the direction of rotation. When this strain is reversed at the back dead centre, and when it is such as to be coincident with the direction of rotation, then the crank is freed perfectly from the shaft and allows the projectile to be forced unimpeded forward. The pitman has a slot in it so that if the projectile is arrested in its work before the end of the stroke, the crank, owing to its momentum, will fly past the other dead centre and go as far up on its withdrawing stroke as the length of the pitman will admit, at which point it is instantly engaged with the rotating power shaft, and compelled to make the remainder of its compression stroke without waiting or standing at that point an instant. When this compression stroke is completed at the back dead centre it is again automatically released and another powerful blow delivered. The blow of the pick is very great and is well adapted for undercutting in hard clay or coal. It stands the hardest usage which has been given it.

Another advantage of this machine is that the cost of installing one or more in a given mine is materially less than the cost of placing one or more air machines in the same mine. A small dynamo, costing $800, resting on the floor of the shop or engine-room, takes the place of the heavy air-compressor, costing $3,600, and requiring a heavy and expensive foundation. Any ordinary engine can be used to run the dynamo, or water makes a desirable and economical power. An engine to run ten machines with a capacity of 1,100 tons per 10 hours costs $400. The wires are run in the entries in a few hours' time, and replace the expensive air pipes. There are no joints to be repaired or to be kept tight. Lights for the mine may be run from the same wires, and it has been suggested that the town be lighted by the same plant at evening, giving an additional revenue.

The following are some data furnished by Mr. Elmer A. Sperry, inventor of the machine, which will be of interest :—

At dynamo on surface	2·55 horse-power.
Watts dynamo on surface	1,579 watts.
Watts motor at face	1,532 watts.
Length of circuit	3,200ft.
Furnished to drill	1·73 horse-power.
Drop in transmission	2·25 volts.
Amperes (constant current)	20 amperes.
Efficiency of motor	85 per cent.
E.M.F.	80 volts.

THE LONDON COUNTY COUNCIL AND THE METROPOLITAN ELECTRIC LIGHTING SCHEMES.

The following is the letter addressed by the Board of Trade to the County Council in reply to their letter of the 6th ult. The Chairman of the Highways Committee, Mr. Benn, and one of the members of the Committee, have been requested to confer with the Board of Trade, with a view to amendments being made in the Order.

Board of Trade (Railway Department),
London, S.W., 13th June, 1889.

Electric Lighting Acts, 1882 and 1888.

Sir : I am directed by the Board of Trade to acknowledge the receipt of your letter of the 5th inst., and to request that you will convey to the County Council the thanks of the Board of Trade for the valuable assistance they have given in the matter.

The Board of Trade have considered the several suggestions made in your letter, and I am now to enclose a copy of a Model Order which they propose to follow in all cases of applications in the metropolis now before them.

With reference to this Order and the representations contained in your letter, I am to make the following observations :—

1. The Order to the London Electric Supply Corporation will be granted only on the condition that they provide duplicate sets of generating machinery and a duplicate set of mains in order to secure a proper and continuous supply in case of a breakdown of machinery or other defaults. And regulations will be subsequently issued to guard against danger to the public from currents of high tension.

2. Streets will be scheduled in the several Orders for the compulsory laying of mains, and provision is made for supply on proper requisition and on equitable conditions within the rest of the area of supply. There will be one exception to this rule. In the parish of St. James, the vestry have advised the Board of Trade that no streets should be scheduled, and, looking to the nature of the parish, the Board of Trade propose to defer to the opinion of the local authority in this respect.

3. Provision is made for the revocation of the Order, in case of default, in respect of the whole area, or, with the consent of the Undertakers, in respect of a part of the area, and that the consumer shall be called upon to bear only the cost of so much of any service line as exceeds 60ft. from any distributing main.

4. Provision is made for the removal within two years of all overhead wires erected by the companies, and for possible forfeiture of the Order if they invade or continue to invade a district within which they have no statutory power.

5. The proposed Clause 55 of the London Company's Order has been struck out.

6. The Board of Trade proposes that the Model Order shall be closely followed in all Orders, and, so far as possible, in all licenses granted in the metropolis.

7. Provision is made to extend the Metropolitan Subways Act, 1868, to electric lines where any subway has been constructed within the area of supply. But as regards future subways, and as regards the vesting in the County Council of the power to make subways in the London streets, the Board of Trade are of opinion that these are matters which cannot be dealt with by them in a Provisional Order. The same remark applies to giving a veto to the County Council on the opening of thoroughfares.

8. And as regards the exemption of the Council and vestries and district boards from liability in respect of damage done to mains in carrying out works of repair, and in the use of steam rollers, the Board of Trade think that if any change is made in the present legal position it should be dealt with by Parliament in a measure of general application.

9. In addition to the provisions for the protection of sewers contained in the Gas Works Clauses Act, which are incorporated with the Electric Lighting Act, provisions have been inserted in the Model Order for the protection of sewers from the operation of all works in their proximity.

10. Provision is made for the revision of price at the end of seven years on conditions to be then fixed by the Board of Trade. The Board of Trade, in the absence of accurate information as to the facilities for and the cost of supply of energy, think that it would not be reasonable to fix now the scale to be made applicable seven years hence.

11. Provision is made to prevent the acquisition without the consent of the Board of Trade by one company of the undertaking of another, and the association of one company with another supplying or intending to supply energy. But the Board of Trade do not think that they could properly propose to Parliament that Parliament should part with its own powers of dealing with any future proposal to extend the statutory area of supply of any company.

12. The price to be charged to local authorities is to be made the subject of agreement.

13. The minimum charge for supply is fixed at 13s. 4d. a quarter.

14. The Board of Trade concur in the view that, as far as is consistent with the principal Acts, there should be one controlling authority ; and, with this object, they have vested in the County Council the appointment of inspectors to—(*a*) Inspect lines and works. (*b*) Test currents. (*c*) Certify meters as being of a pattern approved by the Board of Trade. (*d*) Take proceedings.

15. The cost of providing adequate testing stations will devolve on the companies.

Digitized by Google

16. But the Board of Trade do not consider that they could properly insert in a Provisional Order, or in a Bill confirming a Provisional Order, a clause or clauses limiting or determining the powers of purchase given by the general statute to local authorities. The Board of Trade admit the force of the arguments which may be used in favour of setting up one purchasing authority for London, but they are clearly of opinion that this can only be done by a general Act.

In drafting the Model Order, it will be observed that the Board of Trade have given effect, in all cases where it was possible for them to do so, to the wishes of the County Council, whose desire to facilitate the working of the companies' undertakings under proper safeguard of the public interests they fully recognise.

In apportioning the areas, the Board of Trade have departed very slightly from the recommendations contained in Major Marindin's report. It has been the earnest object of the Board of Trade to give effect to the views of the various local authorities. But it has been found impossible in the apportionment to carry out in detail all the wishes of the local authorities severally concerned. The Board of Trade have had to regard the Metropolis as a whole, and they are pleased to observe that the County Council support generally the recommendations as to area made by Major Marindin.

In conclusion, I am to state that it is most desirable that the Provisional Order should be confirmed by Parliament this year, and they propose to introduce the necessary Confirmation Bill at the earliest possible date after the reassembling of Parliament on the 17th inst.—I am, Sir, your obedient servant,

COURTENAY BOYLE.

The Clerk to the London County Council.

REPORT ON THE FIRST SIX MONTHS' WORKING OF THE ELECTRIC AND ALLIED TRADES' SECTION OF THE LONDON CHAMBER OF COMMERCE.

We have been furnished with a revised copy of the report prepared by the Secretary, which was read at the meeting of the Section on Monday, 24th ult., and ordered to be supplied to the Electrical and Engineering Press:—

"This Section was finally organised at a meeting of the trade held on the 22nd October, and a Working Committee was then elected. The Committee was divided into the following sub-sections:—Telegraph Companies, Telephone Companies, Electrical Manufacturers and Contractors, Electricity Supply Companies, Consulting Electrical Engineers, and General Engineers. The Electricity Supply Sub-Section was the first to get to work; on the 16th November it met, and considered the relations between the supply companies and the local authorities in regard to Licenses and Provisional Orders. It recommended the Executive Committee to memorialise the Board of Trade that the unit should be increased from 1,000 to 10,000 watt-hours, also there should be united action on the part of Undertakers in dealing with the question of paying the legal expenses of local authorities, as in some cases such payments had been demanded. It also asked the Committee to urge all the Electric Supply Companies to stand firm on the question of declining to sell undertakings at a shorter period than the 42 years' limit obtained under the recent Act, that Supply Companies should require two years as the minimum period in which compulsory work should be carried out, and that the model forms of accounts and general regulations for the Electric Supply Companies proposed by the Board of Trade should not be issued until the Supply Companies had been at work for at least a couple of years, in order that these rules and forms of accounts might be issued after reasonable experience had been obtained to suggest the best form for them. These recommendations were confirmed by the Committee at a subsequent meeting and communicated to those interested in the trade.

"Early in the year a Sub-Committee was appointed to consider the proposal of pushing the question of obtaining a Government laboratory for standardising electrical measuring instruments, and it was decided to take common action with the Institute of Electrical Engineers. Accordingly a Joint Committee was appointed, which met several times, and eventually, on the 19th June, an influential deputation representing the Chamber of Commerce and the Institute of Electrical Engineers attended at the Board of Trade, and laid before the President a scheme and estimate for such a laboratory. The deputation was favourably received, and there is every reason to believe that the matter will no longer be shelved.

"The question of overhead wires was taken up on the 4th February by a Committee appointed to examine the matter. This Committee held several meetings, and eventually has succeeded in obtaining a copy of the draft regulations intended to be issued by the Board of Trade for the regulation of overhead wires. The Committee hope to be able to obtain some modification of some of the more stringent regulations proposed by the Board of Trade, and which appear to press hardly on the trade. At any rate, they have good reason to believe that their representations will secure the issue of the rules in a modified form for country installations.

"A Committee was appointed to see whether some modification of the Chamber of Commerce rules respecting arbitrations could not be made so as to invite members of the Electric Trade Section to avail themselves largely of such arbitrations as a convenient method of settling disputes in the trade, and eventually the permission of the General Council was asked to the following modification:—That as disputes on electrical matters at present were somewhat complicated and involved much expert knowledge, disputants should, if they so agreed, be permitted to avail themselves of the services of counsel and expert witnesses in arbitrations otherwise under the Chamber's rules.

"A Committee was appointed to consider whether a standard form of specification could not be drawn up for the convenience of consulting electrical engineers on the lines of the specification very generally used by architects and builders. It was found, however, that for the present such a form of specification was not generally called for, and the idea was abandoned.

"The question of the railway rates under the new Railway Act was considered as far as it referred to electric trades. A Sub-Committee prepared a report on this subject, which was presented to the General Committee on the 13th of May, and it was subsequently revised according to the form adopted by the Chamber of Commerce generally, and finally lodged by the Board of Trade and railway companies on the 3rd of June.

"The Electrical Section enjoys great advantage in such cases in being able to avail themselves of the great experience and *prestige* of the Chamber of Commerce itself on a matter which so greatly affects the future commercial interests of every member of the trade.

"After the experience gained during the first three months the Committee of the Section decided that the amount of useful work done could be greatly increased if the Section secured the services of a gentleman thoroughly acquainted with the trade, to act as the Section's correspondent, and after due permission had been obtained from the Council of the Chamber it was decided to ask Mr. Trotter to accept the post. Mr. Trotter kindly consented to this, and the result has been shown in the greatly increased volume of the useful work which has passed through the hands of the Committee since the date of his appointment."

PARLIAMENTARY INTELLIGENCE.

The Government and the Telephone Companies.

In the House of Lords last night,

The DUKE OF MARLBOROUGH rose to call attention to the negotiations stated to be going on for an amalgamation of the principal telephone companies in the kingdom, and to move that the Post Office withhold any consent to the establishment of such a monopoly before a Joint Committee of both Houses of Parliament shall have considered the general conditions under which the telephone companies at present carry on their business, and the right by which either telephone or electric light companies have been establishing a gigantic public nuisance by the running of overhead wires in all directions across main thoroughfares, and have considered further whether it would not be advisable for the Government to establish a general system of telephonic communication throughout the country in connection with the work of the Post Office. This subject, the noble Duke said, had not been discussed in either House of Parliament, but it was one of great public importance. Notice had appeared that it was the intention of the principal companies to amalgamate and form one large system for the purpose of carrying on telephonic communication throughout the country. When the United Telephone Company was introduced, the Government, exercising their powers, claimed the rights of the telephone as being part of the purchase of the telegraph companies, and, being successful in litigation, an arrangement was come to by which the Telephone Company were allowed to carry on the business on payment of royalties. The time had now come when the patents were about to expire; and it appeared to himself and many others that the Government should lose not a moment in determining the attitude they meant to adopt towards the telephone companies. It might be supposed that in view of the unremunerative bargain made with the telegraph companies the Government would not be disposed to encourage the telephone companies; but that policy would be suicidal. Telephonic communication would never be successfully established in this large and important city, and throughout the country generally unless the Government were prepared to take up the question. They now had the means of doing it. They had a reversion of this valuable invention, which was already the subject of an established provisional experiment, by means of which the United Telephone Company

Digitized by Google

had developed a system, not in itself complete, but more or less efficient. There were, however, many gaps in the system; there were delays in obtaining communication, the whole of which resulted from the great disadvantages under which telephone companies laboured—the difficulties of obtaining way-leave and those other disadvantages ever present to a private company in the establishment of a great net-work of communication, without having absolute rights upon which it could work. At present there was no controlling authority in respect of overhead wires; and no private individual could object unless he could show that his freehold was interfered with. As a consequence telephone and electric lighting wires were being run up in every direction, absolutely disfiguring the metropolis and increasing the danger of locomotion. In this respect, matters had come to a point; and he asked whether the subject should not be considered by a Joint Committee of both Houses. The telephone had been so improved that it could be utilised over a distance of one hundred miles; and in a small country like England there would be no difficulty in connecting many of the larger towns, thus giving an enormous advantage to commerce. Such a system could not be carried out by a private company. The Government alone was able to undertake the work and develop it and make it prosper, as had been demonstrated by the Parcels Post system. Another consideration for the proposed Committee was the question of way leave. In the face of the great experimental work carried on by the telephone companies, wires had been run in all directions, and in the course of time some prescriptive right might be claimed for this peaceful occupation. A similar position might be taken up by the electric lighting companies acting under Provisional Orders. In an old town like London it was impossible to lay all these wires under ground. The trenches required, even in modern cities in America, were very large. Enormous difficulties were encountered in running overhead wires owing to the hostility of owners of property. The Grosvenor Gallery Electric Lighting Company was the most successful in London, chiefly because it had been able to depend almost entirely on overhead wires, and he was bound to confess that in a place like the metropolis he did not believe it would ever be possible to supply the subsidiary force required in electric lighting without overhead wires. The Joint Committee would do well to consider the rules and regulations under which overhead wires should be erected. One suggestion was that lines of communication should follow lines of streets; that derricks should be of strength and weight sufficient to carry the cable swinging between; that the swing of the cable should not be excessive, and should not cross main thoroughfares except at stated points.

The MARQUIS OF SALISBURY said that the fact that the patents would expire in the course of a short time made it necessary for the Government to determine what course they would pursue. He did not think it desirable to examine the points at issue between the Government and the companies, because they were matters to be considered by the Committee, and he would probably prejudge the case. He could only say that the Government had no objection to the proposal in the first part of the noble Duke's motion. He (the Marquis of Salisbury) was not sure that the second subject ought to be adopted as part of the same inquiry. It seemed to belong to the jurisdiction of those who exercised power over public thoroughfares. In any case the noble Duke would find the inquiry sufficiently protracted on the first issue to occupy the Committee for the remainder of this Session to induce him to confine it to that point.

LORD BALFOUR OF BURLEIGH thought it extremely desirable in future discussions to separate more than the noble Duke had done the two subjects of telephone communication and electric lighting wires. Their lordships should be reminded that the Bill amending the Electric Lighting Act of 1882 conferred special powers on the Board of Trade for regulating overhead wires for electric lighting. These regulations were in an advanced state of preparation, and as soon as possible they would be communicated to Parliament. By the Provisional Orders obtained under the amended Act of last session, electric lighting companies in the metropolis were required to remove overhead wires within a specified time, and that arrangement was in process of being carried out without undue hardship on the companies. As to the Grosvenor Gallery Company, they had acquired a site at Deptford, where extensive operations were to be conducted, and it was anticipated that within a reasonable time it would be possible to arrange for the removal of a large number of overhead wires. As to the telephone companies, it was perfectly true the Board of Trade had no authority to deal with them.

The DUKE OF MARLBOROUGH said he was impressed by the advice of the Prime Minister as to the advisability of confining the reference to the Committee, to the adoption by the Post Office of the telephone system, although he thought there was plenty of time for inquiry, seeing that the patents did not expire for two years.

The MARQUIS OF SALISBURY: At the end of next year.

The DUKE OF MARLBOROUGH added that if the Committee commenced its sittings next Session there would be time to secure legislation. As to the works at Deptford, it might be possible to bring a current of 4,000 volts by underground wires, but it was in distributing the force into 2,000 volts over a wide area that the necessity for overhead wires arose. It was necessary Parliament should deal with this question of overhead wires. There was no city in civilised Europe so behindhand as London in telephonic communication, and certainly none so absolutely spoilt and disfigured by wires running in all directions.

The MARQUIS OF SALISBURY said it was certainly desirable that Parliament should be in a position to legislate before the conclusion of next Session.

The DUKE OF MARLBOROUGH said he would withdraw his motion with the view of proposing it at the beginning of next Session.

The motion was accordingly withdrawn.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 22, 1889.

A great deal of interest is being taken at the present time in this country in the subject of submarine cables. It is observed that there is great activity in bringing cable schemes before the public, and there is good reason to believe that we are about to enter upon another season of activity, both in Atlantic and Pacific waters; but nobody can see where the United States are likely to reap any profit or glory whatever out of the work. In view of the prodigious quantities of cable turned out here for aerial, underground and submarine work, it is a little strange that America has done practically nothing in the department of deep-sea cable laying. It is to her credit, of course, that she has given her liberal support to cable projects from time to time, and we are not likely to forget the pioneer work of Mr. Cyrus Field. But it does seem as though, in an electrical country like this, we ought to have succeeded in securing some contracts for deep-sea work. At the present time the project of a cable from the United States to Brazil has been revived by the Brazilian Government itself, apparently with every likelihood of carrying the scheme through. Then we have the Chilian Government advertising in our daily papers for contracts for a cable to be laid around the Straits of Magellan, while a new cable is talked of to be built by German capital from Ostend to Portland, Maine, and a Pacific cable is talked of and subscribed for to connect San Francisco with the Sandwich Islands. Then there are two or three Canadian projects, and the new cable from Halifax to Bermuda. Thus it will be seen that, as you may have already noted in England, the air is full of cable projects, and while some of these schemes may come to naught it is tolerably certain that others will be carried out. Perhaps with the record of so much honourable achievement in other electrical fields, America might well let England alone in her hitherto unquestioned supremacy in cable-laying enterprises, but I really should not be surprised if American capital were found entering the lists to secure a part of the work. With regard to the Brazilian cable, it will probably be remembered by some of your readers that a company named the Pedro Segundo was formed some time ago in this country, to carry out the work under what is known as the Cummings Concession. It is now understood that this Concession has lapsed, but it seems likely that Americans will after all try to control this cable, which is of so much importance to American political and commercial interests.

Some extent to which electric lighting is carried on board American vessels may be formed from the superb new steamer "Puritan," which begins this week to ply through the Sound between New York and Fall River. This passenger boat is undoubtedly by far the finest specimen of marine architecture of her class afloat. A great many English electricians have navigated the waters of the Sound on board the older steamer of the line, the beautiful "Pilgrim," and they will perhaps remember that on board that vessel not only was electricity the sole reliance for lighting the interior of the steamer, but that it was applied to all the side, head and steering lights. When this was done four or five years ago it was regarded as a pretty hazardous piece of work, and cautious people thought that the steamship company ought to have some sort of lighting provision other than electricity in reserve. The results have vindicated the courage and skill of those who made the Edison installation on board the "Pilgrim," and now we find the larger, and even more magnificent "Puritan" fitted out on the same lines electrically, her sole dependence for illumination being upon an Edison plant of 1850 lights driven by special Armington-Sims engines. In the "Puritan," moreover, some very novel effects in the way of illumination have been attempted and successfully carried out.

We have lately had some very interesting tests made here in regard to work and efficiency of electric roads. I believe I have before remarked on the fact that owing to the newness of this industrial department it has been difficult to get at satisfactory

Digitized by Google

figures with regard to the cost of operation by electricity and the economical results obtained by the substitution of electric motors for horses, steam, locomotives, or the cable. One good test was made a short time ago on the Daft-road at Asbury Park, the figures of which I mentioned in this letter. A test which goes even further has recently been completed by Dr. Louis Bell, of Purdue University, Lafayette, Indiana, on the Sprague electric road in that city.* This road operates a little more than 3½ miles of single track on the Sprague system. It was run by horses until the middle of the summer of 1888, and has now been operated electrically for about eight months. It includes grades of 6 or 7 per cent., and one 7·34 per cent. grade on a stretch 800ft. long, while there are at least a dozen curves, most of them of short radius. There are seven motor cars on the road, of which six are in continuous service. The plant is driven by two Edison dynamos, each of a normal capacity of 30,000 watts at 500 volts, and it is worthy of note that there are two other Edison machines of about half the capacity in the same station supplying current to stationary motors for manufacturing purposes, &c., at about 250 volts. This plant is driven by a Hamilton-Corliss engine, 14 by 36in, running at 88 revolutions a minute, taking steam from two large horizontal boilers, at a normal pressure of 85lb. Each car makes from 35 to 40 miles per day, and is operated by one man. The tests applied under these conditions brought out some interesting figures. It appears that the amperes on the car line varied from 0 to 90 and the volts from 405 to 480, averaging about 450, a sudden call for a large current invariably lowering it to about 410 volts. The electrical output varied also greatly during the different hours of the day. It was found that the amount of power actually needed on the average to operate the line was exactly 2½ electrical horse-power per car; but the efficiency of conversion from the indicated horse-power at the engine to the electrical horse-power did not average more than 40·7 per cent., though it rose to a maximum of 65 per cent. at one time. At Richmond, on the Sprague-road, the diagrams made showed that the power required there approximated to 4 to 5 electrical horse-power per car, but the Richmond cars are much larger and heavier than those of Lafayette. The coal burnt during the day at Lafayette was 4,500lb. of slack, which was at the rate of 7·3lb. per indicated horse-power per hour, or nearly 16lb. per electrical horse-power per hour. As Dr. Bell shows that there was a further efficiency on the line of over 90 to 95 per cent., while the motors may be depended upon for an average of 80 per cent. on the level and 70 per cent. on sharp grades, the dynamo running at an efficiency also of at least 90 per cent., it will be seen that such a coal consumption is larger than is permissable or warranted. The fluctuations in the power required are necessarily enormous and very frequent, and hence with engines set for economical work at one fixed load, the conditions become wasteful. Dr. Bell further points out that the direction in which to work to increase the efficiency of the electric motor is decidedly more in the direction of adopting the steam-engine to this class of work than in attempting to increase the already remarkably high electrical efficiency. The problem he presents is that of working the engine on an average at its most economical point of cut off, while combining with that feature the power of expanding to sudden, though very brief demands for several times the average horse-power consumed. As to the results obtained with the road in general, Dr. Bell points out a number of excellent features, and says very pertinently that the live question to-day does not involve the chances of the electric road, but the fading hopes of its competitors. He points to the number of roads on which electricity has replaced horses, and says that while no inroads have yet been made on cable systems it is open to doubt whether they can hold their own even in the favourable localities where they are already established. Dr. Bell also points out that while all traction systems are liable to occasional mishaps there are many advantages in favour of electricity, one of which is the great power of varying the speed. Another point, which he does not include in his list, I notice, is that of backing the car. In this respect the cable car is helpless and hopeless, and the ease with which the electric car can be stopped and reversed never fails to make a most favourable impression on street railway men. Altogether, Dr. Bell's investigation is one of the most thorough and exhaustive yet made in this line of work.

An interesting form of meter has just been patented by Mr. Gustav Pfannkuche, who is now connected with the Brush Electric Company of Cleveland, and who has already done some important work in regard to distribution and measurements. In this new instrument of his Mr. Pfannkuche resorts to the principle of the well-known thermopile in an ingenious manner. The thermopile, or thermo-spiral, which he adopts is acted upon by the heat generated by the current in the main circuit, and the current which has thus been generated in the thermopile is measured in a suitable galvanometer in the ordinary manner. In the operation of this apparatus the current to be measured, or a portion of it, is first converted into a thermo-electric current, the thermopile practically answering in function to a converter, the primary coil of the thermopile being represented by a heat bar or device through which the current to be measured is passed. As variations of heat applied to the alternating joints of the thermopile produce variations in the current generated, so the variations of the currents to be measured by this new instrument are indicated by the variations in the strength of the thermo-electric current.

[* We reprint this article in another column, but our correspondent's excellent summary will be found to give all the most salient features.—Ed. *E.*]

CORRESPONDENCE.

SUPPRESSING SPARKING IN ELECTRO-MAGNETS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your 14th June number (Prof. Thompson's Paper) an electrical device is mentioned at bottom of page 151 of "layers of foil between the windings," and stating further that "this method was patented by Paine and Frost in 1870, and rediscovered by Prof. Arons in 1887."

This arrangement was well known some years earlier than the dates given. It was one of two methods recommended by myself to the Electric and International Telegraph Company for the purpose of delaying the demagnetisation of a certain part of the translating apparatus employed on long lines. I believe one form is still in use for the same purpose in the Postal Telegraph apparatus, and is mentioned by Mr. Preece in his Paper on Shunts, read before the Society of Telegraph Engineers.

The effect of both methods was to reduce the spark, and at the time delay the demagnetisation.—Yours, &c.,

17 and 18, Cornhill, E.C., F. Higgins.
1st July, 1889.

COMPANIES' MEETINGS & REPORTS.

The United Telephone Company (Limited).

An extraordinary general meeting of this Company was held yesterday at the City Terminus Hotel, Cannon-street, Mr. James Braud presiding.

The SECRETARY (Mr. Thomas Blaikie) having read the notice convening the meeting,

The CHAIRMAN said that the meeting was purely a formal one called for the purpose of confirming resolutions passed at the last meeting. Since that meeting the only matter of importance that had occurred was the writing of a letter to the secretary by the Postmaster-General, which letter was published in the newspapers, which he had no doubt they had all seen, as well as the reply to it on the part of the Directors, who naturally felt that they had had the best of the correspondence. Since then the Postmaster-General had written another letter, which was also published, but to which they did not deem it necessary to reply, thinking it better to leave the public to form a judgment as between the telephone companies and the chief of the Post Office. The Directors were doing what they believed they had a perfect right to do. They were not seeking to interfere with the Postmaster General or the Government in any way whatever. Their object in amalgamating was to make themselves stronger financially, and in other ways. Furthermore, they wished to give a better and cheaper telephonic service to the public. He then moved *seriatim*, and Mr. J. S. FORBES seconded, the confirmation of the following resolutions,

Digitized by Google

which were passed at the ordinary meeting of the Company on the 4th prox.:—

"*That the agreement submitted to this meeting, and expressed to be made between this Company and the National Telephone Company (Limited) for the amalgamation of the two Companies, by a transfer of the business and property of this Company (with certain exceptions) to the National Telephone Company (Limited), in consideration of shares in that Company be and the same is hereby confirmed.*

"*That with a view of giving effect to the above-mentioned agreement, and in order to enable the shares to be allotted thereunder to be distributed among the members of this Company, this Company be wound up voluntarily, under the Companies' Acts, and that Mr. Thomas Abercrombie Welton be, and he is hereby, appointed liquidator for the purpose of winding up its affairs and distributing its property.*

"*That pursuant to the 161st Section of the Companies' Act, 1862, the Liquidator be, and he is hereby authorised, to carry the said agreement into effect, and to receive the shares agreed to be allotted thereunder and to distribute the same, together with the shares of the National Telephone Company (Limited), already held by this Company, in specie, among the members of this Company.*"

The resolutions having been unanimously agreed to,

The CHAIRMAN said it was his painful duty to bid the shareholders good-bye as Chairman of the Company. He had occupied the position ever since the Company was started. Before that period he was Chairman of the Bell Telephone Company, who first introduced the telephone into this country. He, and a few friends, some of whom he saw around him, bought the wonderful instrument from Prof. Bell. They found it, however, impracticable for the commercial working of the exchange system, and so they joined with Mr. Edison and his friends and bought up the property of the Blake transmitter, working ever since under the title of the United Telephone Company. He had had, therefore, the pleasure of presiding over the Company in its boyhood, in its youth, and its lusty manhood, and now he was helping them to do that which was good for all strong men, namely, to get married. He had had the pleasure of seeing their shares go from £5 to £15 and their dividend from almost nothing to 17½ per cent., so that he thought he was entitled to regard his record with satisfaction. He hoped that the shareholders would think that on the whole he had served them well. On the new company they would have a very excellent board, they would be all men well qualified to conduct their affairs with success. He did not know who was to be Chairman, but his task would be somewhat easier than what the board of the United Telephone Company had to face when they began their enterprise.

Mr. F. FAITHFULL BEGG expressed his regret at the decision of the Chairman, which he said took all the shareholders by surprise.

Mr. J. W. BATTEN also said it was a matter of surprise to him that Mr. Brand should come to such a determination. From the very day that Mr. Brand joined the Company to the present time the telephonic industry had never been absent from his thoughts. He had devoted all his time and energy to it, and he (the speaker) hoped that the meeting would ask Mr. Brand to still continue to be on the Board of the new Company.

Mr. D. PARRISH and Mr. W. CUTHBERT QUILTER, M.P., having also expressed their regret at the Chairman's decision,

The CHAIRMAN said that he was very grateful for the handsome way in which his past services to theCompany had been referred to. He did not intend on that occasion to enter into any of the reasons which had made him come to the conclusion he had done. If the meeting of the United Telephone Company had requested him to reconsider his intention, of course it would have been his bounden duty to do so, and he would have had the greatest pleasure in endeavouring to meet the wishes of those whom he had tried to serve so well; but the matter did not depend on the shareholders of the United Telephone Company. A request of that kind would have to come from the representatives of the new company.

Col. R. RAYNSFORD JACKSON proposed a vote of thanks to the Chairman not only for presiding over the meeting, but for the services he had rendered to the shareholders and the country in promoting telephonic enterprise.

Mr. J. S. FORBES said he was very reluctant to take part in the discussion. The announcement of Mr. Brand's retirement from the Board of the newly-constituted Company came upon the speaker as a surprise. Mr. Brand's connection with the Company had been so long and so well known, that it required no eulogy from him. The shareholders had had ample opportunities from the results of his administration of forming an opinion of their own on that subject. The speaker wished, as a matter of feeling, that Mr. Brand had been able to put them a little more fully in possession of the reasons, which had satisfied his mind that, on the eve of so important an event as the absorption of three companies by one, he should withdraw his services from the concern. The speaker thought it would be undesirable that a discussion, as to the constitution of the new board, should take place at a public meeting; but he would go so far as to echo the feeling expressed by Col. Jackson, and to appeal to Mr. Brand to reconsider his decision—at all events, until he heard what the feelings of his various colleagues in the new company might be, and what precise position they would assign to him in the new company. Mr. Brand's resignation would, he was sure, prove very embarrassing to his colleagues.

The CHAIRMAN said that he was very much gratified by the kind words that had fallen from Mr. Forbes, and after a brief consultation with those who had been so long connected with him on the Board of the United Telephone Company, he had come to the conclusion to let matters stand as they were for the present. It would be the last thing in his mind to put his colleagues to any inconvenience.

Mr. FORBES then formally seconded Colonel Jackson's motion, which was cordially passed, and

The CHAIRMAN having briefly replied, the proceedings terminated

The National Telephone Company (Limited).

An extraordinary general meeting of the shareholders of this Company was held yesterday at the City Terminus Hotel, Cannon-street, Colonel R. Raynsford Jackson presiding.

The SECRETARY (Mr. William B. Campbell) having read the notice calling the meeting,

The CHAIRMAN proposed—

"*That the following Agreements be and the same are hereby adopted and confirmed, viz.:—*

"(a) *An Agreement made between the United Telephone Company (Limited), of the one part, and this Company of the other part, for the transfer of the United Company's business and certain property to this Company for shares in this Company.*

"(b) *An Agreement made between the Lancashire and Cheshire Telephonic Exchange Company (Limited) of the one part, and this Company of the other part, for the transfer to this Company of the business and certain property of the Lancashire and Cheshire Company, for shares in this Company.*"

Mr. GARNETT seconded the resolution.

The CHAIRMAN, in reply to Mr. Buchanan, said that the recent correspondence in *The Times* on the part of the Post Office officials had caused the Directors no anxiety whatever, and had not influenced them in departing from the course which they had already mapped out for themselves. Neither did they think that there was any reason why the shareholders should trouble themselves in the matter. He anticipated that the Postmaster-General would content himself with the protest he had made, and probably, if, hereafter, he resolved to buy the telephone companies, he would refer the matter to the arbitrator. They were aware that if the Postmaster-General should resolve at the first break in the period of the license to buy the telephone systems, the price to be paid for them would have to be fixed by an arbitrator, and the speaker had no doubt that the Postmaster-General was preparing for himself a series of arguments to influence the decision of the arbitrator. He looked upon the action of the Postmaster-General as having no object beyond that.

Mr. F. R. LEYLAND said he would like to say that this matter had been carefully studied by all the Directors before entering into it. The first thing that naturally presented itself to them was this question, "Will the adoption of the proposed scheme in any way imperil our license?" They took the very best advice they could get on the point. They consulted two of the leaders of the Chancery bar, Sir Horace Davey and Mr. Rigby, Q.C., and their advice was that there was nothing whatever in the license that would be infringed or affected in the slightest degree by the proposed scheme being carried out.

The motion was then agreed to.

The CHAIRMAN moved and Mr. BRUCE seconded the next resolution, as follows:—

"*That the capital of the Company be increased by the sum of* £3,250,000, *by the issue of* 650,000 *new shares of* £5 *each.*"

The motion was agreed to *nem. con.*

The CHAIRMAN moved and Mr. GARNETT seconded the next resolution, as follows:—

"*That the regulations of the Company be varied by substituting for the existing Articles of Association, the Articles, a print of which is now submitted to this meeting, signed for verification by the Chairman of the meeting and the Secretary, and that such last-mentioned Articles be the regulations of the Company in the place of the existing regulations.*"

The CHAIRMAN proposed and Mr. LEYLAND seconded the following resolution:—

"*That in order to give effect to the new regulations of the Company, all the directors holding office prior to their adoption be removed from office.*"

Mr. W. A. SMITH proposed—

"*That Charles Swain Agnew, Esq., John Winterbotham Batten, Esq., James Brand, Esq., John Bruce, Esq., James Staats Forbes, Esq., Peter Garnett, Esq., Eli Heyworth, Esq, Colonel Robert Raynsford Jackson, Frederick Richards Leyland, Esq., Joseph Bond Morgan, Esq., Dillwyn Parrish, Esq., William Cuthbert Quilter, Esq., M.P., George Hunter Robertson, Esq., Samuel Herrick Sands, Esq., and Alderman Joseph Thompson, be and they are hereby appointed directors of the Company.*"

He had never seen, he said, a stronger board to guide the destinies of a company, and on that account they had great prospects of success.

The resolution, which was seconded by a shareholder, was carried unanimously, and the proceedings terminated.

The West African Telegraph Company (Limited).

The fourth ordinary general meeting of the Company was held at Winchester House, Old Broad-street, on Tuesday last, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. Wm. Payton) read the notice convening the meeting and the minutes of the third ordinary general meeting.

The following is the report of the Directors for the year ending December 31, 1888, which was taken as read:—

The gross receipts, including the balance brought down from last account (£1,215. 9s. 11d.), amount to £56,530. 12s. 11d., the general expenditure being £20,016. 0s. 7d. There remains a balance of £36,514. 12s. 4d., which has been applied by the Directors in the following manner:—After providing for debenture interest £15,000 paid and accrued, £5,000 has been carried to repairs and renewal account, and it has also

Digitized by Google

been considered advisable to write down the preliminary expenses by £259. 2s. 8d. These deductions leave an available balance of £16,255. 9s. 8d., from which the directors propose to carry £5,600 to the debenture redemption account, and recommend the payment of a dividend for the year 1888 of 5s. per share, free of income-tax, absorbing £5,777. 5s. 0d., leaving £4,878. 4s. 8d. to be carried forward to the next year's account.

The Company's cables are in good working order, the Bolama-Bissao Cable referred to in the last report having been repaired. Since the last report, this Company has laid a cable (202 knots in length) between Bonny and Prince's Island at a cost of £24,200, which will appear in the accounts for 1889. Cables have been laid by the Eastern and South African Telegraph Company between Loanda and Cape Town, thus completing telegraphic communication along the West Coast of Africa and establishing duplicate and alternative routes to the principal stations of the Company and to the Cape. The laying of these cables adds greatly to the security of the system in point of interruption of traffic. Arrangements have been made between the companies interested for working South African traffic in friendly alliance. In view of these important matters, and the transfer to the Eastern and South African Telegraph Company of a large amount of the share capital of this Company, the Board has been reconstituted, and Sir John Pender, K.C.M.G., Sir James Anderson, and James Pender, Esq., have been appointed Directors in place of three of the former Directors who have retired. The meeting will be asked to confirm these appointments.

The Directors who retire by rotation are Sir Henry C. Mance, C.I.E., and Robert Kaye Gray, Esq., and who, being eligible, offer themselves for re-election.

The CHAIRMAN: Gentlemen, before I ask you to approve of the resolution which I shall propose, I think it right that at this, the first important meeting of this Company, I should make a few remarks, but they will be very few compared to the important work that has just been completed—probably one of the most important works that have been done in connection with submarine telegraphy. If you look at the map behind me you will see that we have virtually surrounded Africa with submarine telegraphs, and we have at the same time connected every port of that great Continent with the great system of submarine telegraphy throughout the world. That is a very great enterprise in every sense of the word—great for the future of Africa, because every one is now endeavouring to take a part in opening up what has been called "the dark Continent"—and I think that we, the submarine telegraphists, have been, as we have been on many other occasions, ahead of every other party who have been attempting to do their part in the development of that vast country. Now there can be no complaint of any want of immediate and rapid communication. To complete that work, starting from England, it has taken no less a length of cable than 18,722 nautical miles. That has not been done by one company, but by a combination of companies; but the policy of the companies over which I have had the honour to preside for so many years has been to recognise that the union of companies gives strength to the general system, and I think the result of this combination will go to prove to the shareholders, as well as to the world at large, that this has been a great work done in that direction. This union will add strength to the system, and what is better than all, I believe it will enable us to pay a very respectable dividend, which, had we all been acting apart, would have been very doubtful indeed.

Sir JAMES ANDERSON: Almost an impossibility.

The CHAIRMAN: Quite so. Some of the great submarine telegraph systems have been carrying out this great work. The Eastern Company's portion of it has been 3,687 miles, that of the Eastern and South African 5,829, that of the Brazilian Submarine 1,824, that of the West African 2,306, that of the African Direct 2,739, and that of the Spanish National 1,837 miles, making altogether 18,722 miles. It is an undertaking that has now been brought into a great system, acting under a joint arrangement and a joint purse, and I believe that the result of the policy will be satisfactory to all parties concerned. I think I may close my remarks by saying that when we conceived this policy of union there were many difficulties to overcome, but I am bound to say on the part of the different companies concerned whose interests were identical with our own—that is to say, that we might work for obtaining the best dividend—that we found them most friendly and well-disposed, and they all admitted that coming into the great chain of the system of telegraphs, having the Eastern Company at the head of it, was not a bad omen for the success of the Company. With these remarks I beg to move:—

"*That the report and accounts for the year ended 31st December, 1888, submitted to this meeting be, and they are hereby received and adopted, and that a dividend be declared payable on and after this date of 5s. per share, free of income-tax, equal to 2½ per cent. for the year.*"

Sir HENRY C. MANCE seconded the motion, which was carried unanimously.

On the motion of Sir HENRY C. MANCE, seconded by Mr. R. K. GRAY, the appointment of Sir John Pender, Sir James Anderson, and Mr. James Pender as Directors of the Company was unanimously confirmed.

The CHAIRMAN: I thank you, gentlemen, for the honour you have done me in reappointing me a Director of this Company. As you are very well aware the Company required to be reconstituted, at least the Board did to a certain extent, and while we regret the absence of the gentlemen who retire, and whose places we have taken, I think they agree fully with us that such reconstruction was necessary so as to work the combined system in perfect harmony. The next motion which I propose is

"*That Sir Henry C. Mance, C.I.E., and Robert Kaye Gray, Esq., be and they are hereby elected Directors of the Company.*"

These gentlemen were directors of the original Company, and by the reconstruction that has now taken place this is a general appointment by the shareholders.

Sir JAMES ANDERSON seconded the resolution, which was carried unanimously.

On the motion of Mr. ALEXANDER HENDERSON (a shareholder), seconded by Mr. ANDERSON (another shareholder), the auditors to the Company, Messrs. Deloitte, Dever, Griffiths and Co., were appointed at an annual remuneration of 50 guineas.

The CHAIRMAN: Allow me to say in regard to the appointment of these gentlemen to the position of auditors that they have been associated with all the other companies. Messrs. Kemp, Ford and Co. were the previous auditors to this Company, and I had an interview with the head of that firm the other day and he himself entirely approved of the change now made. It was a change that we were very adverse to making, but as there was a general reconstruction going on Mr. Kemp said to me that he thought the change a wise policy, though at the time he experienced regret at having to retire from a company which he felt was going to be a prosperous one. I replied that it could not be more painful to him than it was to us. I am glad to see a member of that firm here to-day, and I believe he will agree with me that this change has been carried out amicably and well.

Mr. WILLIS said he had been asked by Mr. Kemp to apologise for his not being able to attend the meeting.

On the motion of Mr. HENDERSON, seconded by Mr. ANDERSON, a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN: I am very pleased that that resolution has been proposed by Mr. Henderson. I think the very first transaction we had in bringing this thing about was with Mr. Henderson himself. I, therefore, feel that he had a great deal to do with this Company, and I am pleased to see him here to-day, believing, as I do, that he has now, as I have, the most perfect belief that this is the beginning of a series of meetings that will be very satisfactory to all concerned. I think we may say that we have got our foot on the ladder. It is not a large dividend that we are

declaring to-day, but the arrangements we have made are such that I believe when we next meet we shall be able to declare what I may call a very respectable dividend. I beg to thank you on behalf of my colleagues and myself.

The proceedings then terminated.

NEW COMPANIES REGISTERED.

CAMBRIDGE UNIVERSITY AND TOWN ELECTRIC LIGHTING COMPANY (LIMITED).—Registered by W. T. Bowman, 2, Earl-street, Cambridge, with a capital of £50,000 in £5 shares. Object, to carry on at Cambridge the business of an electric light company. There shall not be less than three nor more than seven directors. The first to be appointed by the subscribers to the memorandum of association. Qualification, £250 stock.

THE ELECTRIC TRUST (LIMITED).—Registered by Hughes, Masterman and Rew, 59, New Broad-street, E.C., with a capital of £60,000 in £10 shares. Object, the construction, contracting for, establishment and carrying on of works, machinery and apparatus for lighting streets, &c., by electricity. There shall be, until otherwise determined, eight directors. Qualification, £2,000 stock. Remuneration, £50 each.

THE NORTHERN ELECTRIC WIRE AND CABLE MANUFACTURING COMPANY (LIMITED).—Registered by Godfrey, Rhodes, Firth and Co., 77, Chancery-lane, W.C., with a capital of £20,000 in £5 shares. Object, to carry into effect an agreement, dated June 20, made between Blakey, Emmott and Co. (Limited), and J. Duff, and to carry on the business of insulated wire and cable manufacturers. There shall not be less than three nor more than five directors, the first to be appointed by the subscribers to the Memorandum of Association. Qualification, 100 shares. Remuneration, £2. 2s. for every attendance for each director residing within 90 miles of the place of meeting, and £4. 4s. when residing more than 90 miles. Every director is also to receive £20 for every 1 per cent. of dividend above 10 per cent.

THE SERIES AND GENERAL ELECTRIC TRACTION COMPANY (LIMITED).—Registered by Norton, Rose, Norton and Co., 10, Victoria-street, S.W., with a capital of £200,000 in £1 shares. Object, to acquire the patents, property, goodwill, business, undertaking, and assets of the Series Electrical Traction Syndicate (Limited), or any part thereof, and certain patents or rights or interests therein, belonging to H. Foote and C. Von Buch. There shall not be less than four nor more than 12 directors. Qualification, 300 shares. Remuneration, chairman, £500; other directors £250 per annum.

BIRMINGHAM HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—This company was registered on the 26th ult., with a capital of £100,000, in £5 shares, 100 being founders' shares, to form centres in Birmingham, or elsewhere in the United Kingdom, at which electric power may be generated, accumulated, and distributed. The subscribers are :—

	Shares.
Robt. Hammond, 117, Bishopgate-street, electrical engineer	1
Charles Cornish, 132, Belvedere-road, Lambeth, clerk	1
James Whitehead, Heycot, Crouch-end, electrical engineer	1
T. E. Towerson, F.C.S., 1, Portland-road, Finsbury-park, analytical chemist	1
W. J. Bingham, C.E., 7, Bedford-place, W.C.	1
H. Linklater, 117, Bishopgate-street, accountant	1
H. Mann, 12, Woburn-place, Russell-square	1

The number of directors is not to be less than three, nor more than seven; qualification, £250 of share capital; the subscribers are to appoint the first, and are to act *ad interim*. The holders of the founders' shares will be entitled to elect one director, and the House-to-House Electric Light Supply Company (Limited) will also be entitled to be represented on the board. The board will be entitled to a remuneration of £500 per annum, together with one-tenth of the net profits remaining after payment of 7 per cent. upon the ordinary share capital, provided that the whole remuneration shall not exceed £1,000 per annum. The founders' shares will be entitled to one-half of the surplus profits remaining after payment of a non-cumulative dividend of 7 per cent. per annum upon the ordinary shares.

The following companies have also been registered with similar capital, &c., to the Birmingham, for carrying on electrical business in the places and districts referred to in their respective titles. The subscribers and arrangements for management are the same in each instance as in the Birmingham Company :—

Lancashire and Cheshire House-to-House Electricity Company (Limited)—Capital £100,000 in £5 shares.

Liverpool House-to-House Electricity Supply Company (Limited)—Capital £100,000 in £5 shares.

Manchester House-to-House Electricity Company (Limited)—Capital £100,000 in £5 shares.

Midland House-to-House Electricity Company (Limited)—Capital £100,000 in £5 shares.

South of England House-to-House Electricity Company (Limited)—Capital £100,000 in £5 shares.

Yorkshire House-to-House Electricity Company (Limited)—Capital £100,000 in £5 shares.

Scottish House-to-House Electricity Company (Limited)—Capital £100,000 in £5 shares.

The Irish House-to-House Electricity Company (Limited)—Capital £100,000 in £5 shares.

The Northern House-to-House Electricity Company (Limited) is also registered, and the subscribers differ only in the substitution of the name Mr. P. A. Latham, of 15, St. Helen's-place, E.C., for that of Mr. W. J. Bingham.

The Western House-to-House Electricity Company (Limited), has the same capital and subscribers as the Northern.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 28, 1889, amounted to £3,156.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of June, 1889, amounted to £1,600, as compared with £1,690 last year.

THE EASTERN TELEGRAPH COMPANY (LIMITED).—This company announces that subject to the final audit the accounts show, after placing about £118,000 to the reserve fund, a balance available sufficient to pay at the general meeting on 18th July inst. the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the Preference Shares, less income tax, and a final payment of 2s. 6d. per share, with a bonus of 3s. per share, both free of income tax, on the Ordinary Shares, making with previous payments on account a total distribution of 6½ per cent. on those shares for the year ended 31st March, 1889. The traffic receipts of this company for the month of June, 1889, amounted to £44,805, as compared with £48,086 last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of June, 1889, amounted to £39,350, and to £41,764 in the corresponding period of 1888.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—This company has declared an interim dividend of 12s. per share, payable on the 16th inst.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 28, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,017.

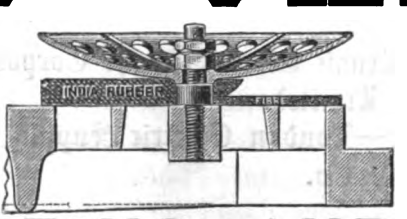
WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the month ended 30th June, 1889, amounted to £6,500.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this company for the half-month ended June 30, 1889, amounted to £2,750, as compared with £2,578 for the corresponding period last year.

THE SERIES ELECTRICAL TRACTION SYNDICATE.—This syndicate, which has demonstrated the applicability of its system to railways and tramways at Northfleet, has now been reconstituted in a larger form. Negotiations have been entered into with several leading tramway and railway companies for the adoption of the system. The company is being brought out privately under influential auspices.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Johnson & Phillips.
Nalder Brothers & Co.
Paterson & Cooper.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 582.—Vol. XXIII. FRIDAY, JULY 12, 1889. Price Fourpence.

NOTES.

During the last week of June, notices of intention to apply for Provisional Orders were served upon local authorities in no less than sixty-one instances, and probably some others have still to come to light. This sudden outburst of activity is, of course, due to the fact that July 1st was the latest date upon which such notices might be served in order to be immediately proceeded with. It is worthy of note that these thirty-three applications relate to only twenty-five towns—Edinburgh, for instance, having attracted six applicants; Glasgow, eight; Cheltenham and Dover, five each; Darlington, three; Birkenhead, Buxton, and Wolverhampton, two. It seems highly probable, therefore, that the Board of Trade Inspector will have his hands very full indeed for some time to come.

The most notable thing about the discussion on overhead wires in the House of Lords last Thursday week was the studious moderation of the speakers, who, notwithstanding their manifest disgust at the "gigantic nuisance," were content to recommend merely a strict regulation of its growth. The Duke of Marlborough himself suggested that the line of wires should follow the line of the street, and should not cross except at stated points. As regards electric lighting wires, Lord Balfour's announcement that the Board of Trade's regulations are on the point of being issued was deemed satisfactory; and there seemed to be a general agreement that in the case of neither of these classes of wires could the overhead system be altogether avoided.

Touching the telephone companies' amalgamation scheme, to protest against which the Duke of Marlborough's motion was primarily aimed, the formal authorisation by the shareholders had been given that same afternoon, and it was therefore little use interfering then, even if the Government could have done so effectually. It seems pretty clear, however, from the words let fall by Lord Salisbury—speaking probably for the Post-master-General—that the Government is looking forward to next Session as a crisis when the affairs of the telephone companies in relation to the Post Office may be usefully inquired into by a Parliamentary Committee.

Mr. Brand's resignation seems to have been as genuine a surprise to the shareholders as it was to the outside public. Rumour has it that the titular headship of the combined companies having been withheld from him he declined to accept any subordinate position, and consequently decided to retire altogether from the management. We can hardly credit this explanation, for Mr. Brand has been so prominently identified with the rise and progress of telephony, and with the steps which have led to the present amalgamation, that a position in it identical with that which he has so long occupied in the parent Company seems to be his of right. Any way, his retirement is to be deprecated, and we hope that it may be averted.

The telephone question in France has met, so far as the Chamber of Deputies is concerned, with a very prompt settlement. On Saturday "urgency was decreed," and on Wednesday the Chamber adopted the Bill for the purchase of the telephone lines by the State. It remains to be seen whether the shareholders of the Société Générale des Téléphones, whose bold resolution passed at a recent meeting we printed last week, will in face of the vote of the Chamber continue the fight they have commenced in the Courts of Law. The question has throughout been discussed with considerable acrimony and personal feeling, in marked contrast indeed with the courteous tone which has up to the present characterised the discussion on the same subject on this side of the channel. It is doubtless very mortifying for the shareholders to have their property summarily purchased for little more than two-thirds of what they consider its proper value; but as we have remarked before, the blame rests with those who entered into an agreement with the State capable of being interpreted in a manner so disadvantageous to the company.

As will be seen in another column, Major Marindin has advised the Board of Trade that it would not be expedient to accede to the request of the Dublin Gas Company to be allowed to exercise its power of breaking up the streets for the purpose of electric lighting. This decision is what reasonably might have been expected. It would be obviously unfair to hamper electric lighting companies proper with all manner of restrictions, and allow gas companies to enter into the business without Licence or Provisional Order. But for the fact that the Dublin Gas Company's original Act had been amended in 1883 the Corporation would probably have been obliged to contest their claim in the Law Courts. As it was, by the Act of 1883 the permission of the Board of Trade was required before the Company could exercise its powers under the 1866 Act. The right of other Gas Companies, possessing similar but unamended powers, to break up the streets for the purpose of supplying the public with "other improved means of lighting," is therefore still untouched.

THE numerous photographs of lightning flashes which have been taken of late tend to show tolerably conclusively that lightning has by no means always the instantaneous character hitherto attributed to it. One of the earliest workers in the field of lightning photography was M. TROUVELOT, and in a short article in *La Lumière Electrique* (*vide The Electrician*, 17th August, 1888, p. 457), he insisted emphatically on the irrefragable nature of the evidence afforded by the camera as to the comparatively lengthy duration of the particular flash to which he was then referring. Subsequent examination of the photograph in question has, M. TROUVELOT states in a recent number of the *Comptes Rendus*, "clearly shown that the multiplication of the image is the result of the displacement of the apparatus while the flash lasted." It seems that a small cloud which crossed the streak of light at the lower end has been found to have undergone identically the same amount of displacement as the flash itself—a fact inconsistent with any explanation other than that the lightning flash was made up either of a number of discharges following one another in exactly the same path, or of a single flash of sensible duration.

A QUESTION, which so far as we know has not before been raised, occurred to us while watching the storm of 6th of June. Of the several hundred discharges which took place during the two or three hours the storm lasted, and of which a large proportion, so far as the eye could tell, were discharges to earth, only some five or six at the most were accounted for the next morning by the outward and visible sign of damage done. What became of the remainder? We shall, of course, be told that the rest went to earth quietly. It must, however, be remembered that a good earth is not afforded either by a slate roof or a stone pavement, yet these are interposed in towns almost everywhere in the path of a flash. This simple fact seems, therefore, to require further explanation.

M. LAGUERRE in the *Revue Internationale de l'Electricité* has proposed a new solution of the old problem of telegraphy without wires, and one which has at least some merit of novelty. Before we expound M. LAGUERRE'S idea we may offer the remark that the perfect realisation of this ideal should carry with it the inestimable boon of establishing unbroken simultaneous communication with any number of vessels at sea, however distant. We forbear to enlarge upon the ideas suggested by this visionary gleam, and will only add that in the present state of electrical science—*pace* M. LAGUERRE—its realisation seems in the highest degree improbable. We may likewise remark that in the days of PHILIP REISS the transmission of speech by electric currents was also considered in the highest degree improbable.

NOW for M. LAGUERRE'S project. If we take two insulated conductors and connect them by a wire, then on imparting a static charge to one a certain quantity of electricity traverses the connecting wire, and its passage may by suitable means be detected. Let the terrestrial globe be one of the said conductors, and as for certain reasons the moon is not available for the second conductor, let us be content with a good big sheet of metal, such as a roof of galvanised iron, well insulated from the ground, but connected therewith by a wire in which our telephone or galvanometer is interpolated. This constitutes our receiver, and if anybody anywhere, according to some preconcerted code, sufficiently varies the potential of the earth's surface we shall know of it. All this can very easily be put into mathematical language, and then, knowing the size of the earth and the smallest detectable current, we can readily calculate how much iron roof and how many volts, or rather what number of coulombs, will be required. M. LAGUERRE'S investigation yields the following results:—Assuming that the earth's surface measures 510,000,000 square kilometres, and that we can detect the passage of one-thousand-millionth of a coulomb, then with an E.M.F. of 1,000 volts at our disposal we must have an insulated conductor measuring five hectares, or 12·36 acres. We also want for transmission under the above conditions a condenser with a capacity equal to one hectare, or 2·471 acres, of surface.—It is to be feared that these statistics can scarcely be held to prove the immediate practicability of the scheme. Some improvement might possibly be effected by the use of alternating currents of Enormous Voltage—but would the Board of Trade consent? Meanwhile, we take leave to congratulate M. LAGUERRE upon a very beautiful and ingenious suggestion, though we fear that for the present ships at sea are as far away as ever.

ACCORDING to *Indian Engineering*, one of the chief items of extra expenditure on the Indo-European Government Telegraph administration for 1887-8 was the sum of £2,129 "For presents made to His Imperial Majesty the Shah of Persia and to some of his ministers on the renewal of the convention by which the British Government is allowed to maintain a telegraph line in his dominion." As nobody seems the least ashamed of the transaction, which is candidly set forth in the annual Report of the Indian Telegraph Department, we can only express our astonishment at the Shah's moderation. All the same, it is satisfactory to note that the Indian Government takes it out of him, or his subjects, for any damage done to the telegraph lines.

ONE of the most successful of the early workers in the field of arc lighting—or rather of the automatic regulation of the arc light—was the late Mr. W. E. STAITE. Unfortunately it is also acknowledged that he derived no pecuniary benefit from his labours, but sacrificed a considerable sum of money upon his devices without any return, the time not being ripe for their application. We drew attention to the facts last year, when his son, the Rev. G. H. STAITE, made an appeal on behalf of the inventor's family; and we are now informed that steps are being taken to memorialise the Government on the subject. Electricians who desire to further the object of the memorial should communicate with the reverend gentleman, whose address is Sutton-Cheney Vicarage, Hinckley, or with Colonel Hill, C.B., M.P.

AT the moment of going to press we learn that the ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION have reclaimed to the First Division of the Court of Session against the judgment of Lord TRAYNER in the Outer House, in the action by KING, BROWN and Co., Edinburgh, to reduce BRUSH'S dynamo patent.

Digitized by Google

The Metropolitan Electric Supply Bill.—This Bill was read a second time in the House of Commons on Monday last.

Cardiff.—Formal notices were received from five electric lighting companies announcing their intention to make application for Provisional Orders.

Wednesbury.—Notices have been received of the intention of the House-to-House Electricity Company to introduce electric lighting undertakings into Wednesbury.

A Correction.—In the list of exhibitors of electrical apparatus at the forthcoming Exhibition at Bingley Hall, Mr. A. A. Goldston's name was inadvertently printed as Goldster.

Insulating Staples.—Messrs. Mosses and Mitchell, of 68-71, Chiswell-street, E.C., have been appointed sole agents for Europe and the Colonies for the sale of Mason's Safety Insulating (Fibre) Staples.

Rifle Firing by Electricity.—The War Office is experimenting with an electrical firing arrangement adopted for use with a rifle. The system has already been tried by the German and Italian Governments.

Rothesay.—At the monthly meeting of the Rothesay Town Council on Monday, an intimation was received from Messrs. Norman and Sons of their intention to apply for powers to introduce electric lighting into the town.

The Electric Light on Railways.—The Paris, Lyons and Marseilles Railway Company have just put on their lines some new first-class carriages lighted by electricity from accumulators fixed beneath the floor of the carriage.

Morecambe.—Sanction has been given by the House of Commons to a Provisional Order of the Board of Trade for the construction of a tramway to be worked by electricity, running from Scotforth, *vid* Lancaster, to Morecambe.

Ward's Electrical Omnibus.—Mr. Ratcliffe Ward and Mr. F. B. Behr have exhibited Ward's Electrical Omnibus to the Shah in the grounds of Buckingham Palace. The Shah was greatly interested in the performance of the omnibus.

The Electric Light in Collieries.—The electric light is now used at the Llay Hall Colliery, Gwersyllt, for the first time. There are 65 lights, some 16 and some 32 candle-power, lighting the pit-head, yard, crossings, offices, and workshops.

Major Marindin's Report.—A Parliamentary Paper has been issued containing Major Marindin's report on the metropolitan electric lighting schemes, and the subsequent correspondence between the Board of Trade and the London County Council.

Central Station at Montlucon (Allier).—A central lighting station of 600-light capacity has recently been inaugurated at Montlucon. The plant comprises a 60 horse-power horizontal engine and two Edison dynamos giving 180 amperes and 105 volts.

An Electric Inspector Wanted.—It will be seen by our advertisement columns that the Liverpool Corporation require an Electric Inspector at a salary of £160 per annum, the person appointed being required to devote his whole time to the duties of this office.

The Post Office Magazine "Blackfriars."—The July number of this magazine maintains its usual standard, and in point of literary workmanship is above the average. Some well-known Postal and Telegraph names are announced as contributors to the next number.

Accidental.—On taking up and repairing the recent fault in the Assab-Massowah cable, belonging to the Italian Government, it was found that the cable had been bitten by a large fish, proof of which had been left behind in the shape of one of the monster's teeth.

Foreign Contracts.—In a return recently issued of all contracts with foreigners entered into by British Government departments within the last twelve months, we notice contracts for projectors and telephones, Mangin mirrors, and various parts of the Hughes' apparatus.

Sheffield.—At the last meeting of the Sheffield Town Council a communication was received from the Electric Construction and Maintenance Company intimating intention of the company to apply to the Board of Trade for a Provisional Order to supply electricity within the district.

Willesden.—Notice has been served upon the Willesden Local Board by the House-to-House Electric Light Supply Company that they intend to apply to the Board of Trade for a Provisional Order for the supply of electric light for public and private purposes in the parish of Willesden.

Rotherham.—At the last meeting of the Rotherham Town Council the Town Clerk stated that two electric lighting companies intended to apply to the Board of Trade for Provisional Orders to supply electricity within the borough. It was agreed that the subject be referred to the General Purposes Committee.

The "Centralblatt für Electrotechnik."—Herr R. Oldenbourg, of Munich, writes to inform us that from the first issue of this journal for July it will be continued weekly instead of, as previously, fortnightly. The new series is increased in size, and is nearly as large as our contemporary the *Electrical World* of New York.

Buxton.—The Electric Construction and Maintenance Company have given notice of their intention to apply to the Board of Trade for a Provisional Order to supply electricity within the district of the Buxton Local Board of Health. A similar notice has been issued by the Municipal Electric Light and Power Corporation.

"The Gas and Water Review."—The *Gas and Water Review*, an old-established journal devoted to the interests indicated, has amended its title by the addition of the words "and *Journal of Electric Lighting*." Our contemporary announces that it will advocate the undertaking of electric lighting business by gas companies.

Dundee.—At the last meeting of the Dundee Town Council the Anglo-American Brush Corporation and the Electric Construction and Maintenance Company announced their intention of applying for Provisional Orders to supply Dundee with the electric light. A Committee was appointed to report what action should be taken.

Bournemouth.—Three companies are about to apply for Provisional Orders with a view to the introduction of the electric light at Bournemouth—the Anglo-American Brush Electric Light Corporation, the Electric Construction and Maintenance Company, and the South of England House-to-House Electricity Company.

The late Mr. Patey.—In the return of Civil List pensions for the year ended June 20th, we are glad to notice the name of Mrs. Helen Patey, who has been granted a pension of £200 in consideration of the services rendered by her late husband, Mr. C. H. B. Patey, in the improvement of the telegraph services of this country.

Hinckley Local Board.—At the last meeting of this Board the Clerk read a communication from the Midland House-to-House Electricity Company stating that it was their intention to apply to the Board of Trade for a Provisional Order, and asking the consent of the Board to the same. The matter was adjourned to the next meeting.

St. Luke's Vestry.—At the last meeting of this Vestry notices were received of application for Parliamentary powers to inaugurate electric lighting in the district from the Metropolitan Electric Supply Company, the London Electric Supply Corporation, and from a firm of solicitors in Fenchurch-street on behalf of a private enterprise.

Grantham.—At the monthly meeting of the Grantham Town Council, on Wednesday last week, a letter was read from the Birmingham House-to-House Electricity Supply Company, giving notice of their intention to apply to the Board of Trade for power to introduce the electric light into Grantham. The letter was referred to the Lighting Committee.

Newcastle.—Last week the report of the Watch Committee relative to the public lighting of the city was presented to the Town Council. Alderman Newton moved its adoption, with a rider that the Watch Committee inquire into and report to the Council on the possibility of illuminating a portion or the whole of the city by the electric light. This was agreed to.

Birkenhead.—At a meeting last week, the Town Clerk informed the Council that notices had been received from two electric lighting companies intimating their intention to apply to the

Digitized by Google

Board of Trade for powers to supply Birkenhead with electric light. The matter was referred to the Finance Committee, who will confer with members of the Gas Committee as to the course to be adopted.

Bath.—At the last meeting of the Surveying Committee of the Bath Town Council a letter was received from the solicitor of an electric lighting company about to be formed, announcing the intention of the promoters to apply for a Provisional Order. There was some discussion as to the validity of a notice from a company which was only about to be formed, and it was finally decided not to acknowledge the receipt of the letter.

Hastings.—At a monthly meeting of this Council held on Friday last, notice was received from the Hastings and St. Leonards Electric Light Company of the intention of the Company to apply to the Board of Trade for a Provisional Order. A similar notice was received from the South of England House-to-House Electricity Supply Company. The matter was referred to the Council in Committee for consideration and report.

Manchester.—A special meeting of the Manchester City Council will be held on the 7th of August, "To take into consideration and determine upon the expediency of applying to the Board of Trade for a Provisional Order under and in accordance with the Electric Lighting Acts, 1882 and 1888, to authorise the supply of electricity by the Corporation of Manchester for public and private purposes within the City of Manchester."

Wolverhampton.—A notice has been received by the Town Council from the Wolverhampton Electric Light and Power Company intimating that the Company intend to apply to the Board of Trade for a Provisional Order authorising them to supply electricity for public and private purposes within the Borough of Wolverhampton. A notice to the same effect has also been received from the Midland House-to-House Electricity Company.

Cheltenham.—Five notices of intention to apply for Provisional Orders to provide Cheltenham with the electric light have been received by the Town Clerk. The five companies sending in these notices are the Electric Construction and Maintenance Company, the Laing, Wharton and Down Construction Syndicate, the Anglo-American Brush Corporation, the Midland House-to-House Electricity Supply Company, and a Company about to be formed.

Catalogue of the Hibbard Electric Manufacturing Company.—The first annual catalogue of the Hibbard Electric Manufacturing and Supply Company of Montreal, although by no means as exhaustive as some of those issued by similar firms in this country, contains a tolerably complete list of the lighter articles of electrical manufacture, such as batteries, bells, pushes, telephones, &c. This catalogue is got up in the artistic style which characterises these publications across the Atlantic.

The London County Council.—At the meeting of this Council on Tuesday last, the Highways Committee reported that several amendments suggested by them with reference to the Model Provisional Order proposed to be adopted with respect to areas of supply in London had been accepted by the Board of Trade. On the recommendation of the Committee the London Electric Supply Corporation were authorised to lay a cable along the subway from the south end of Northumberland-avenue to Trafalgar-square.

Darlington —At a meeting of the Darlington Town Council last week the Town Clerk stated that he had received notice from two or three electric light companies that they intended to apply for powers to light the town by electricity. Some discussion followed, from which it was elicited that the Corporation had obtained powers some time since for applying electricity if thought requisite, but the matter had not been followed up. The subject was finally referred to the Gas Committee.

Exeter.—At the last meeting of the St. Thomas (Exeter) Board of Guardians a letter was read from the Devon and Cornwall Electricity Supply Company, stating that they intended to apply to the Board of Trade for a Provisional Order authorising them to supply electricity for public and private purposes at Heavitree. The Town Council have also received notices of intention to apply for Provisional Orders from the Electric Construction and Maintenance Company and from the Devon and Cornwall Electricity Supply Company.

Perth.—At the monthly meeting of the Police Commission, held last Monday, a communication was read from the Secretary of the Scottish House-to-House Electricity Company, intimating that that company intended to apply to the Board of Trade for a Provisional Order for authority to supply electricity for lighting for public and private purposes within the city, and requesting the consent of the Commission to the application. The letter was remitted to the Police, Lighting, and Fire-Engine Committee, with instructions to bring up a report to a future meeting.

Electric Lighting Activity.—During the past few weeks Messrs. B. Verity and Sons, of Covent-garden, have been exceedingly busy in electric lighting work. Some of the most important orders they have in hand are—Sherborne House, Northleach, Gloucestershire, for Captain L. Byng, Royal Horse Guards; Foots Cray Place, Kent, for Sir John Pender, K.C.M.G.; Riverhome, Hampton Court, for Mr. Osborne O'Hagan; and the Commercial Bank of Scotland. The firm are also busy in the manufacturing departments, having secured the whole order for fittings for the Governor's house at Singapore.

Glasgow.—Notices of intention to apply for Provisional Orders for the public supply of electric light have been received by the Town Council from Messrs. Muir, Mavor and Coulson, the Scottish House-to-House Electricity Company, the Kelvinside Electricity Company, the Electric Construction and Maintenance Company, Norman and Son, the Partick, Hillhead and Maryhill Gas Company, and the Anglo-American Brush Corporation. The documents have been remitted to the Gas Committee. It will be remembered that the Glasgow Corporation itself has announced its intention to apply for a Provisional Order.

Athletic Sports.—The Electric Athletic Club, which represents the telegraphic element of the Post Office, held its annual meeting on Saturday, the 6th inst., at the Paddington Recreation Grounds. The programme included running, walking, and cycling matches, the contests for which were of the usual excellence. Mr. Fischer, the head of the Central Office, presented the prizes. The Post Office Sports are announced for the 27th inst., at the Richmond Athletic Grounds, commencing at 2:30 p m. Lady Turnor has promised to distribute the prizes, and the band of the 7th Surrey Rifles is to play during the afternoon.

Liverpool.—The Watch Committee of Liverpool had before them at their last meeting a letter giving notice of the intention of the Liverpool Electric Supply Company to apply for a Provisional Order; also notices from the following companies of their intention to apply for Provisional Orders—the Electric Construction and Maintenance Company, the Liverpool House-to-House Electricity Company. It was resolved that the Liverpool House-to-House Electricity Company should be informed that the Committee could not consider the question of giving their consent until they had been furnished with a draft of the proposed Order.

Celluvert.—We have received from Messrs. David Moseley and Sons, of Manchester, some specimens of a new substance called "celluvert." The samples before us present the appearance of very stiff, highly-glazed cardboard. Several valuable qualities are claimed for celluvert, such as great tensile strength and high insulation. It can be filed, planed, and shaped, and is but slightly affected by acids and alkalies. The material is made hard or flexible, and can be obtained in sheets, tubes, or sticks. The industrial applications of celluvert will, doubtless, prove numerous. Messrs. David Moseley and Sons are the sole agents in this country for the Celluvert Manufacturing Company of Wilmington, Del.

Dover.—At a meeting of the Dover Town Council last week the Town Clerk reported that five electric light companies—namely, the Electric Construction and Maintenance Company, the Municipal Electric Light and Power Corporation, Crompton and Co., the South of England House-to-House Electricity

Digitized by Google

Supply Company, and the Laing, Wharton and Down Construction Syndicate—had announced their intention to apply for Provisional Orders to supply Dover with the electric light. The Town Clerk was instructed to bring up the report of the 1882 Committee, and to apply to the companies in question for particulars of their proposals.

Business Changes.—We learn that the electric business of the firm of Clarke, Chapman, Parsons and Co. has been transferred by mutual consent to the Hon. C. A. Parsons, the well-known inventor of the Turbo Electric Generator, who will now carry on the whole of their business in connection with electric lighting under the name of Parsons and Co., retaining the entire staff of the department. In addition to the turbo generator, the manufactures of this firm include slow-speed dynamos, arc lamps, projectors for the passage through the Suez Canal, for harbour entering and for war ships, and all other requisites for electric installations on land and on board ship.

Edinburgh.—On Tuesday last week the Town Clerk intimated that six different electric lighting companies had given notice of their intention to apply for Provisional Orders. These were—The Scottish Electric Supply Company, the Scottish House to-House Electricity Company, the Electricity Supply Corporation, the Electric Construction and Maintenance Company, Messrs. Crompton and Co., and the Anglo-American Brush Electric Light Corporation. The notices were remitted to the Lord Provost's Committee, and notice given of a motion remitting to the same Committee to consider the advisableness of the Corporation applying for a Provisional Order to supply electricity for the lighting of the city.

Technical Education in Nottingham.—At a special meeting of the Nottingham Town Council on Monday last week, a letter was read from the Drapers' Company in reference to the proposed extension of the University College at Nottingham by the erection of technical schools. The Drapers' Company offered to provide £3,000, conditionally on the balance of £9,000 being raised by voluntary contributions within twelve months from now. A communication from the solicitor of the late Mr. F. C. Cooper, of Nottingham, was also read, offering to transfer to the Corporation, subject to certain details being arranged, the real and personal property of the deceased gentleman, of the estimated value of £5,000, for the promotion of technical teaching at the University College. These offers were cordially accepted by the Council, and hopes were expressed that the necessary balance would soon be raised.

Hammersmith Vestry.—At the fortnightly meeting of this Vestry last week, the Law and Parliamentary Committee reported that with respect to a circular letter from the Paddington Vestry, transmitting copy of resolutions passed by them dissenting from the proposal to transfer control under the Electric Lighting Act from the Board of Trade and Vestries and District Boards to the London County Council, and inquiring the views of this Vestry thereon, they recommended that the Vestry do agree with the resolutions passed by the Paddington Vestry, and that the Board of Trade, the London County Council and Paddington Vestry be so informed. After considerable discussion the matter was referred back to the Committee for further consideration. Letters were received from the Anglo-American Brush Electric Light Corporation, the London Electric Supply Corporation, the House-to-House Electric Supply Company, the Metropolitan Electric Supply Company, and on behalf of a company about to be formed, stating that application is intended to be made to the Board of Trade for Provisional Orders, authorising them to supply electricity for public or private purposes within the parish.

The Proposed Edinburgh Exhibition.—A meeting of the Executive Committee of the proposed "International Exhibition of Electrical Engineering and Mechanical Inventions, Edinburgh, 1890," was held on Wednesday morning. The various Committees in connection with the scheme were arranged for and the conveners appointed. Among other matters considered were the choice of a general manager. The appointment of agents in London and the Continent was also considered, and it was remitted to a Sub-Committee to arrange for these. Numerous subscriptions, it is stated, have been already intimated from private individuals, and promises of support in the way of exhibits have been received from various parts of the country and the Continent. Among the latter are some important exhibits now on view in the Paris Exhibition. Mr. Edison has also agreed to place some of his inventions on view. On the same afternoon, at a meeting of the Lord Provost's Committee of the Town Council, it was resolved to recommend the Council to decline to grant the East Meadows as a site for the Exhibition. The Lord Provost's Committee at the same time resolved to recommend that the Council should vote a sum of £1,000 to the guarantee fund of the Exhibition, provided the Council were satisfied with the site and other arrangements.

Dublin.—At a meeting of the Corporation of Dublin, on Monday, the Town Clerk reported that he had been served with notices on behalf of the Irish House-to-House Electricity Company and of Colton and Company, intimating their intention of applying to the Board of Trade for a Provisional Order for private and public electric lighting in Dublin. He said the Board of Trade had forwarded the report of Major Marindin in reference to the recent inquiry, at which the Alliance and Dublin Consumers' Gas Company sought powers to open the streets for the purpose of supplying electric light to the St. Stephen's Green area. The report, which was a lengthy one, stated on the subject of capital that even if it were held that the refunded sums should be considered as old capital, which was somewhat doubtful, the amount actually available for electric lighting was only £10,000, and this sum was inadequate for an undertaking which was estimated to cost £15,882. The power to break up the streets would, if granted, place the Gas Company in a far better position than any other electric lighting company in the kingdom, and in a position which he could not think was contemplated by Parliament or the Board of Trade. In conclusion, the Inspector said:—"I have to report that, in my opinion, it is not expedient for the Board of Trade to accede to the request of the Alliance and Dublin Consumers' Gas Company, and to exercise their power under the Act of 1883 by giving permission for the breaking up of the streets by the Company for the purpose of electric lighting."

The Metropolitan Electric Lighting Orders.—On the order for the second reading of the Electric Lighting Provisional Orders (No. 2) Bill in the House of Commons, on Wednesday evening, Sir G. Campbell said he had no desire to stop the progress of these Bills; but he wished to be assured that the section of the Act of 1888 which provided that the consent of the local authority should be obtained before a Provisional Order was granted by the Board of Trade for the lighting of any district had not been forgotten. Sir M. Hicks-Beach said that the Act of last Session was properly stringent upon the point which the hon. member had raised. He thought it was a great discredit to this country that the Metropolis of this great Empire should not before this time have had the advantage of the electric light. He trusted that, while every proper interest would be safeguarded by the Committee to which these Bills would be referred, it would be found possible during this Session to deal with this matter, which might have been dealt with some time ago but for defects in the general law. The hon. member had referred to the objections of the local authorities which they had felt it their duty to overrule as if those objections had been general. That was not the case. It would appear from the special report that in only two cases in the whole of the Metropolis were objections made on any important grounds. The other objections were practically settled, and in the two cases which he had mentioned the objections were not based on matters of principle, but on matters of detail affecting clauses, which matters might be properly dealt with by the Committee. The Bill was then read a second time, as were also three other Electric Lighting Provisional Order Bills. A number of petitions in opposition to several London Electric Lighting Provisional Orders have been deposited in the House of Commons, among them being one on behalf of the Duke of Bedford and the Strand District Board against the Mid-London Order; the Wandsworth District Board of Works petition against the South London Order; the Vestries of St. John the Evangelist and St. Margaret, Westminster, petition against the Kensington and Knightsbridge Order. All the petitioners pray to be heard in Committee.

MODES OF DAMAGE BY LIGHTNING.

BY PROF. OLIVER LODGE.

Some recent occurrences suggest that what experiment indicates to be a possibility does sometimes happen, viz., that electricity surges up from an earth contact by an underground route and causes damage without having any obvious entrance or exit to the sky. When discharge occurs to the ground, conductors, like gas pipes buried in it are so disturbed that they easily give off sparks; not sparks which will charge a Leyden jar—the electricity splashes up and subsides again in an instant,—but sparks which very readily light gas and give shocks.

This is a straightforward experimental fact. One would not, therefore, be surprised to hear of lightning producing a similar effect on a larger scale; so that, when the ground is struck, earth connections of all kinds to neighbouring houses and telegraph stations become sources of danger rather than safety, and bring up from the main flash echoes or splashes which may in some cases do damage.

Three instances, or apparent instances, of this have been reported to me recently. The first is the case of a house at

FIG. 1.

Wavertree, wherein a gas pipe was melted in an underground cellar and the gas ignited, while there was no trace of any kind indicating how the lightning had got to the cellar, except that the owner saw a fireball or glow travelling up the drive, along what turned out to be the course of the gas main. (A fuller account is subjoined.)

The second instance is that of a lighthouse in India, reported to me by Colonel Fraser, R.E., in which while flashes were striking the lightning conductor, a man was killed inside the building, though no apparent branch flash reached him from anywhere. Various explanations of this case may be suggested, and I do not press it, but quote it below.

The third case is that kindly communicated by the Electrician to the Commercial Cable Company, where instruments not connected with any line-wire or cable, but only connected to earth though the lightning protector, were completely destroyed. A record of this may be found in another part of the paper.

Returning to the first, or Wavertree case, the following is a statement by the occupier of the house, E. Lennox Peel, Esq.:—

"One stroke, A (Fig. 1), melted and twisted up 8ft. of roof-gutter round the corner, and also knocked off 2ft. of ornamental finishing, C. At first we thought this was the same stroke as the one that landed (B) in the cellar, *under* drawing-room window, D, fusing 3ft. of gas pipe, firing the gas, and scorching the cellar ceiling; but as we can find no trace of A coming *inside* the house we fancy now that we were hit twice, and that we never saw A at all from the dining-room window, E."

"There were two tremendous crashes, one of which we put down to a stroke on the church exactly opposite, the steeple, with conductor, being just opposite dining-room window, E, across road from the gate shown. At the first crash (but we now believe *before* we heard it) a ball of fire seemed to come away from the church, cross the road, rush through the gates, up the drive, and pass E as if to D. I was standing inside the window E, and saw it coming, but had to shut my eyes. There is a gas lamp opposite right-hand gate-post, and our gas pipes are laid under the drive up to B. The next crash came 30sec. later, and was probably A. Both were distinctly heard in church, as if the house had been struck twice. The steeple was surrounded by black cloud, high up, swirling round, and white vapour low down. The lightning came from every quarter, about nine flashes in less than two minutes, with very large hailstones."

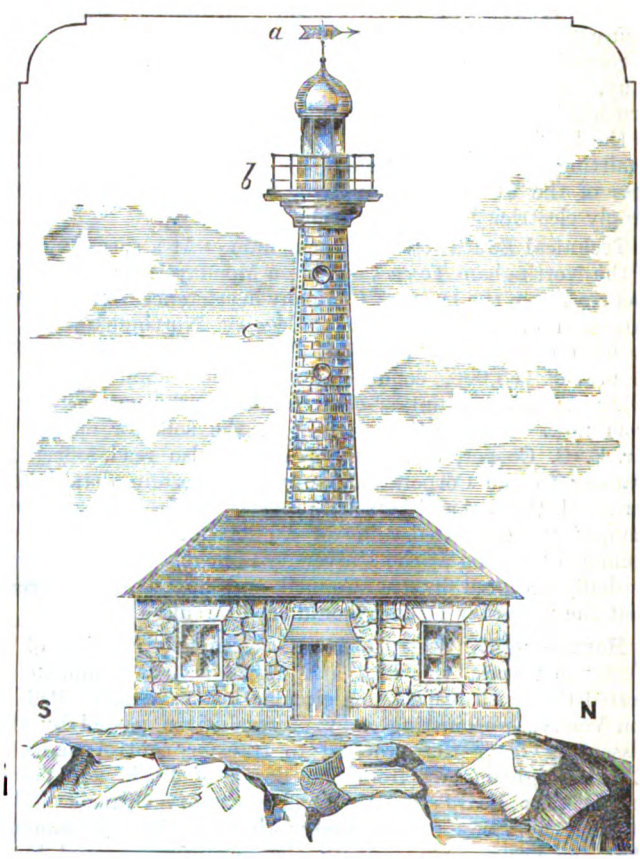

FIG. 2.—Mangatore Lighthouse.

a, copper vane; *b*, wooden railing; *c*, copper wire rope at the back of the tower.

I myself examined the premises some weeks after the event, and it is clear to me that the church was not struck, or, at least, not struck violently. If Messrs. Newall have a record of how this conductor is earthed, and would communicate it, it might perhaps be of interest. The points of its conductor are sharp, and no part of the conductor or earth shows the least trace of damage. The church steeple is lofty and its centre is only 52 yards from the house. The conductor is a copper tape by Newall, of Gateshead, and seems in excellent condition. The house is an ordinary building, not so tall as the body of the church itself; it is, therefore, entirely dwarfed by the spire, and that it should have been struck in preference to the spire is remarkable. Service was going on in the church at the time. There were seven flashes all pretty close together, and two of them were specially loud and alarming. One of them Mr. Peel believes to be connected with the damage to the roof at A; the other to the damage in the cellar at B.

Digitized by Google

The telephone wires from church to a neighbouring house are quite thin and uninjured, and evidently have nothing to do with it. The path of the flash which struck A is not at all clear. It may have gone down a rain side-gutter and water-butt not far off, but if so it has left no trace of its passage. No connection of any kind is apparent between the two damages. And it seems to me much more likely that the second flash got into the gas pipes outside the house altogether. Several feet of pipe had been very effectually fused, but this may have been mostly done by the ignited gas which burned some time before discovered. It was ¾in. pipe—not compo—and it must have been a pretty strong disturbance to melt it.

The ball of fire seen travelling along the ground which often makes its appearance in these stories is too frequently set down to imagination, because it is not a thing to be expected on ordinary theories; but when we know so little of the phenomena, it is surely wiser to accept provisionally even incredible statements, if often repeated, and try and amend our theories by them, rather than to ignore what may turn out to be perfectly true.

It may be remembered that during some of the experiments I had the honour of showing at the Institute of Electrical Engineers, a wire conveying the discharge glowed with a luminous brush all along its length (it is an effect I have frequently obtained in the laboratory), and one of your correspondents (*The Electrician*, May 3, p. 749) wrote to ask about what he likened to a "luminous mouse" which he saw travelling along the wire, and taking an appreciable time in transit.

The *progressive* appearance is doubtless an optical effect, but the luminosity is a reality, and, since it appeared to travel then, so it may easily appear to travel when caused by lightning.

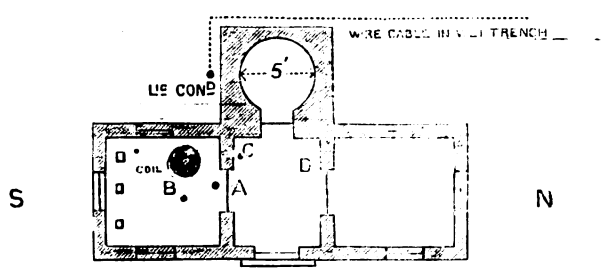

FIG. 3.—Ground Plan of Lighthouse.

A, assistant master's position; *B*, deceased, standing; *C*, inspector; *D*, two other natives.

I should suppose that the gas pipes conveying the discharge are at so high a potential that the brush from them is sometimes visible above the ground. If this be a fact, it is not one that can be regarded as at all established as yet; but this communication may direct observers' attention to the possibility both of this brush effect and also of damage being done by a charge which surges up and subsides again whence it came, without having any separate egress, or, as it has hitherto been usually expressed by observers, without any perceptible ingress to the place where the damage is done.

A fourth instance I have heard of quite recently as occurring at Harvey-road, Cambridge, where damage was done to roof and to basement, but no apparent connection or path from one to the other. I should suppose that the roof damage was done by a side-flash spitting off from the main-flash and returning to it again without finding any separate earth. It is very necessary to realise that this lateral expansion or temporary overflow may occur, so that things are momentarily charged and discharged again without their necessarily affording any thoroughfare whatever.

Perhaps Mr. Glazebrook could find time to report on this case?

The following are the communications from Colonel Fraser:—

PROF. O. J. LODGE, F.R.S. Malabar District, May 29, 1889.

Dear Sir: Having several lightning conductors to do with, and rather inclined to your expressed distrust of them, it may be of interest to mention the particulars of an occurrence at the Mangalore Lighthouse on the 14th inst. This lighthouse (Fig. 2) consists of a masonry shaft about 10ft. diameter, standing on a cubical plinth of 12ft. sides or so, with two small store-rooms having terraced roofs on the flanks. There is a passage in the plinth having an entrance door and doors at the side leading into the store-rooms, and an inner door giving admission to the base of the column which has flights of wooden ladders up to the capital on which there is a gallery and the lantern of glass and bronze.

The Public Works have lately been arranging the lightning conductor, the upper part of which down to the ground was supplied by the English makers of the lantern, and consisted of a 2in. copper wire rope fastened to the exterior of the column and its plinth.

The earth connection only remained, and as the lighthouse is on a dry rocky hill plateau, I had a cable of 49 telegraph wires made at Madras to reach down to a well to be sunk to moist earth in the valley below. When at the place last month this cable had been soldered to the copper rope and laid in an open trench more than 200ft. long to close to the well. As moist ground was not reached at the depth expected the cable was too short, and a piece of extra copper rope had to be waited for as well as the further deepening of the well. From the ground to the top of the lantern is, I suppose, about 150ft., or less.

At 7:30 p.m. a thunderstorm came on it is reported, and as heavy rain fell the trench and cable were wet for a length of more than 200ft., so that the earth connection must have been complete, notwithstanding the cable not ending in the well.

The following extract from the Post Officer's report states what happened:—"A group of natives had been sitting near the lighthouse, and all but two ran for their homes when they felt rain. These two clamoured at the closed door for admission into the lighthouse, in which two keepers had been on duty. On entering the inner room one remained standing, and the other, a youth of twenty-one years, who had lately come up from the Madras College, sat on the sill of the inner door. Before the keeper had time to close the outer door the flash came, the sitting youth fell backwards, and feebly calling for water, died almost instantaneously, his friend was struck up the legs, and was partially paralysed the next day, but afterwards got over it, and the second keeper was hurled across the room. The left arm of the keeper certainly showed marks of exterior burns. No external marks appeared on the dead man." Another account I had from my P.W. subordinate alluded to a small piece of zinc sheeting over the outer doorway as the point the lightning struck.

However, in writing to the head of the Marine Department in reply to inquiries about the lightning conductor, I quoted from your article in *Nature* of March 14 on "Leyden Jar Discharges," which I had been much interested in reading, and its footnote.

I said, in my opinion, as the force of discharge was not in the wire, but in the open air and space (water included) round it, the inside of a lighthouse was a most dangerous place to be in if a flash went through the conductor, as some of the disturbance would go through you.

It is also a question with me if a person, being of conducting material—water, &c.—themselves, they would not spark from induction, much as a piece of metal; and to what extent small masses of metal, such as door locks, watches in the pocket, &c., get charged by a lightning conductor; and there is a third element, the wetted exterior plaster in patches not necessarily continuous.

In my official letter I alluded to the radiations from an electric discharge, and that some of these may have an effect similar to sunstroke upon the human organism—so that radiation and not electricity may have caused the fatal accident.

This was evidently a very bad thunderstorm, as a tree was struck as well as the lighthouse, but the building was unaffected.

The addition of a conductor may have made it proof against being shattered, and at the same time not to be occupied without danger when there is electricity about.

I am inclined to think that the noise of thunder is the radiations made audible much in the mode of your Royal Institution experiment on the C note.—I remain, yours very faithfully,

A. T. FRASER.

PROF. O. J. LODGE, F.R.S. Calicut, June 13, 1889.

My dear Sir: After writing, I have received detailed accounts for which I called, and as no conclusions can be drawn from an inaccurate description, enclose nearly all my official letters, putting the Marine Department at Madras right in their facts.

The statements of the two educated natives, one of whom was struck, are interesting, but contain so little more than I have extracted that I do not trouble you with them.

The lightning conductor evidently was acting, and is said to have been struck twice, as well as a tree three or four hundred yards away.

I find the lighthouse rooms are tiled, not terraced. It is possible they were terraced within my recollection, as the present tiles are certainly new. An amended sketch is enclosed.

Digitized by Google

There is a sheet zinc hood 4½ft. by 3ft. over the front door, and there were 23 of the patent clay tiles, each 6½lb. weight, blown away at the eaves just above the hood.—I am, yours very faithfully,

A. T. FRASER.

Extract from official letter June 12, 1889, embodying the narrative of two native eye witnesses in Mangalore Lighthouse on May 14 when struck by lightning, to correct the first account sent to the Marine Department, Madras.

1. The detailed account of Inspector Ram Rao, one of those in the Mangalore Lighthouse during the thunderstorm of 14th May, differs in some particulars from the information the Post-Officer was able to obtain and communicate.

2. Including the keeper, there were ten natives inside the basement, seven in the passage, two in the south room, and one upon its doorway or sill (Fig. 3).

3. The inspector was on a seat in the passage, near the door leading to the column, which was closed. The front (outer door) was also shut and bolted.

4. The first thing he observed was a "spark"—no flash struck anywhere—on the ground before him about a foot and a-half from his seat. No lightning was seen by him to come through the front door. The electricity was on the floor of the passage, not far from the door of the column.

5. Assistant-master Narani Rao, Government College, also gives an account of what he saw happen, he being on the door sill.

6. He says two people in the passage suddenly saw a light creeping on the floor near their feet, and about the same moment a long spark in the south room; two saw the luminous body on the floor, and two the spark in the room, but only one saw both.

7. Simultaneously with the latter, the narrator and the native who died both dropped on the ground. His impression was that a current of electricity was flowing from his feet to his head, and he soon recovered. He is satisfied that the current did not come through the front door. Singularly enough, the deceased was talking to him about lightning conductors, and asked if his keys were likely to attract it, just before he was struck, without noticing he was standing close to a large coil of wire.

8. Those who saw the spark in the room are positive it was not parallel to the floor. One thinks it was perpendicular, and the other slightly inclined to the lightning conductor outside.

9. It seems there was a coil of 94ft. of galvanised iron fencing wire lying in the corner of the south room, some 5ft. in direct distance from the conductor outside with the wall between.

10. I would be inclined to attribute one of the individuals being fatally struck to his standing near this loose metal, and there were also some kerosene tins in the room, all either inductive or conductive surfaces.

11. But I have to notice that, strictly speaking, none of them had a right to be admitted into the lighthouse on the occasion, and it was, unluckily, one of the worst places they could have chosen in which to take refuge, and there is no system of lighting conductors, which, in my opinion, can make it safe.—A. T. F.

SINGULAR CASE OF DAMAGE FROM LIGHTNING AT A CABLE STATION.

During a severe storm at Canso, N.S., the Commercial Cable Company's instrument-room was recently traversed by a discharge which severely damaged the apparatus, and this, notwithstanding the fact that the earth connections had been broken. The details were carefully recorded by the company's officers, as will be gathered from the following letters, in which the circumstances are fully set forth. The first letter is addressed by Mr. Gott (the chief electrician of the Commercial Cable Company) to Dr. Oliver Lodge, to whom, with Mr. Gott's approval, we are now indebted for its appearance in our columns. We may hazard the suggestion that the damage was due to a "side-flash" from the conductor to the recorder rather than to the main flash striking the recorder first and then jumping to the conductor, as suggested by Mr. Gott. But Dr. Lodge will, we hope, express his own opinion on this point.

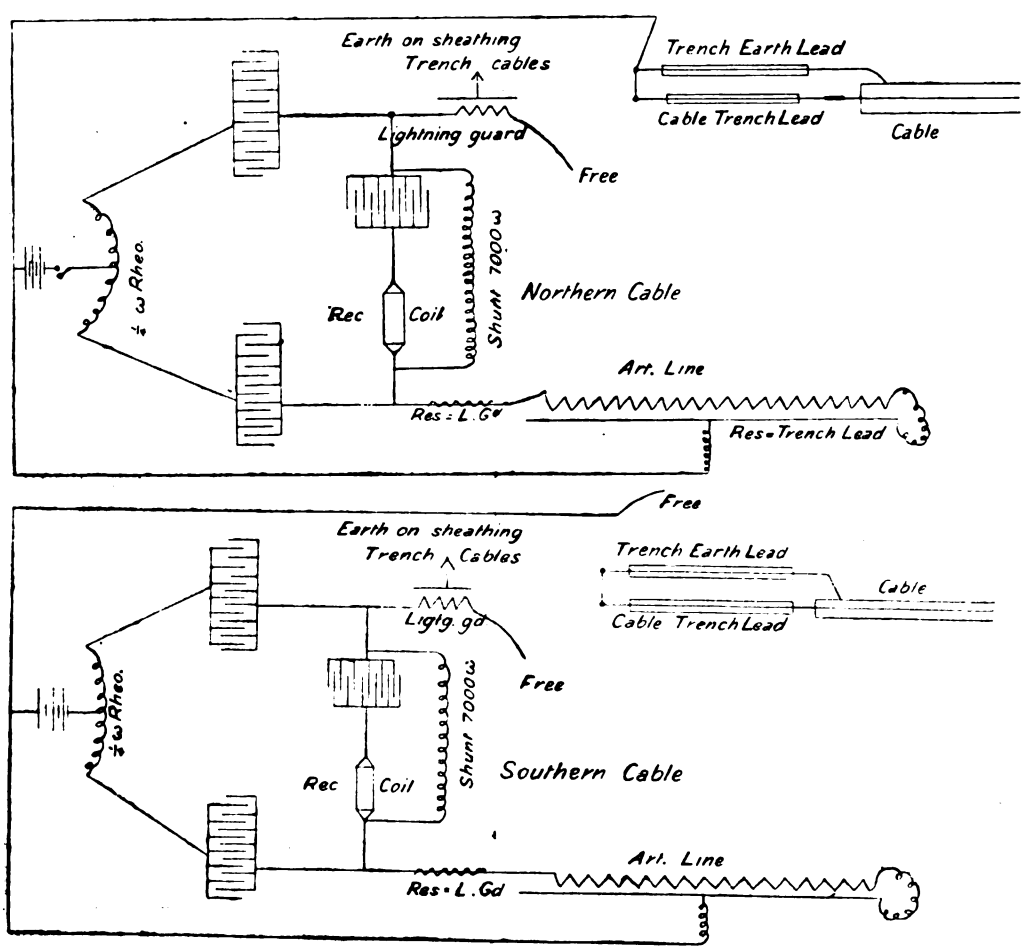

FIG. 1.

16, Mark-lane, London,

PROF. O. LODGE, June 18, 1889.

Dear Sir,—Perhaps you will be interested to see the enclosed report from our superintendent, Mr. Dickenson, at our station at Canso, N.S.

That station was visited by a severe thunderstorm on the 14th of May last, and serious damage was done to the apparatus employed on our northern and southern Atlantic cables. The cables were disconnected from the apparatus and put to earth before the storm.

In the case of the northern cable, the artificial cable was connected by its earth side to the trench wire, which makes earth at the cable house about four knots from the station. This trench wire is in reality a cable with iron wire sheathing, and passes through wet land; or, in other words, the sheathing makes good earth all the way.

In the case of the southern cable the apparatus was entirely cut off from all lines, the only earth in its immediate vicinity being that of the lightning protector.

The Thomson permanent magnet recorder is used on both cables, and in both cases the movable coil was fused and the condensers were damaged.

My own opinion at present is that the lightning struck direct at the large mass of metal of which the recorder is composed, and from these made for the lightning protector. Had there been no lightning protector it is probable the apparatus would have been spared.

This is a well-certified instance of telegraph apparatus being damaged when entirely disconnected from the line, and also one proving that the lightning protector *may* do more harm than good.—I am yours faithfully,

J. GOTT,
Electrician Commercial Cable Company.

Canso,

JOHN GOTT, ESQ. 25th May, 1889.

Dear Sir: I herewith enclose diagram (Fig. 1) showing position of affairs when apparatus was damaged by lightning on the 14th inst. I

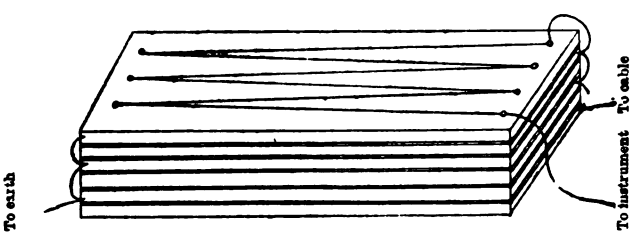

FIG. 2.

was absent from the station at the time, and did not return until four or five hours after damage was done, but careful inquiries lead me to believe that the positions of leads as indicated in diagram are correct. The earth lead was inadvertently left on the northern apparatus, providing a possible path for discharge through the apparatus to lightning guard, and thence to sheathing earth; but no such path appears to have been provided in the case of the southern, which sustained equal damage with the northern.

On the northern, signalling coil and lightning guard were fused, a one-microfarad section of condensers in cable sending block destroyed (short-circuited), and a five-microfarad section artificial line block damaged. Insulation reduced to 15,000 ohms.

On the southern, signalling coil and lightning guard were also fused, and two ten-microfarad sections of cable-block destroyed.

The fine platinum wires in lightning guards were entirely dissipated.

Owing to violent kicks cables were earthed as per accompanying diagram ten minutes before thunderstorm broke over the station.

The lightning guards consist of a fine platinum-wire of about 35 ohms resistance, and a series of thin brass plates separated by mica sheets and alternately connected with cable and sheathing of trench cable (Fig. 2).

The lightning which did the damage appears to have been very close to the station, as the men tell me that the flash and thunder were almost simultaneous. There are somewhat sensational accounts given by some of the men who claim that an electrical discharge seemed to dart across the operating room from one side to the other. My opinion is that they were deceived consequent upon the intense light caused by fusing of coils.

No damage whatever was done on short cable circuits, which were all treated in same way as northern and southern.—Yours truly,

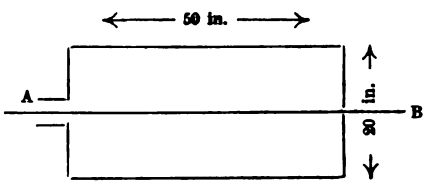
S. S. DICKENSON,
Superintendent.

EXAMINATION PAPER OF THE SCHOOL OF ELECTRICAL ENGINEERING AND SUBMARINE TELEGRAPHY.

At the recent Midsummer Examinations connected with the well-known school in Hanover-square, the following Paper was set for the advanced students; the examiner in electrical engineering being Mr. Gisbert Kapp:—

At least five questions to be answered, but more if possible.

1. A rectangular wire coil of the dimensions shown, and mounted upon an axis, A B, is revolved at a speed of 10 revolutions per second in a uniform magnetic field of 1,000 C.-G.-S. lines per square centimetre. The lines of the



field are at right angles to the plane of the paper. The coil contains only one turn of wire Give the E.M.F. generated when the plane of the coil is at right angles to the lines, when it forms an angle of 45deg., and when it is parallel with the lines. Give the law according to which the E.M.F. varies with the angular position of the coil.

2. A disc machine, gramme-wound, is revolved at 800 revolutions per minute in a 4-pole field. The armature contains 312 turns of wire, and the total number of useful magnetic lines coming out of, or entering into, each of the four-poles is 3,000,000 C.-G.-S. lines (500 English lines). There are four brushes, opposite brushes being coupled together. What E.M.F. will be generated, and what would be the E.M.F. if the same armature were revolved in a 2-pole field, the useful induction of each pole being also 3,000,000 C.-G.-S. lines?

3. What do you understand by (*a*) the ordinary (or external) characteristic of a series machine; (*b*) its total (or internal) characteristic; (*c*) its characteristic of magnetisation; (*d*) its critical speed for a given total resistance; (*e*) its critical total resistance for a given speed? Explain the critical speed in a shunt machine.

4. Explain a method by which the characteristics of a dynamo can be predetermined from its design.

5. A motor (shunt-wound) runs, when doing no work, at 700 revolutions per minute. Its armature has a resistance of ·085 ohm, the field-magnet has a resistance of 25 ohms. The motor receives current from a pair of mains, between which a terminal E.M.F. of 100 volts is maintained—What will be the speed and electrical efficiency when the motor is giving 5 horse-power and when it is giving 9 horse-power? Assume, for the sake of simplicity, that there are no other besides the purely electrical losses—in other words, that the electrical efficiency and the commercial efficiency are equal.

6. Describe and illustrate by hand-sketches various machines used for incandescent lighting (not high-tension arc light machines) having armatures of the closed coil type and of flat ring or disc form, cylinder or Gramme-form, and drum form. Compare the relative merits of the different machines as regards such points as weight, speed, efficiency, and mechanical strength?

7. Describe and illustrate by hand-sketches the Thomson-Houston high-tension arc light machine, and explain its working?

8. You have to transmit 40 horse-power over a distance of 1,000 yards. At the generating station there is to be one series-wound machine driven at a constant speed, and this must give sufficient output that, after allowing for losses in transmission and in the motor, 40 horse-power may be actually available. The motor is also series-wound. What current and E.M.F. would you adopt? What should be the size of the conductor? What type of dynamo and motor would you adopt?—and what must be the relation between them in order to cause the motor to run at a constant speed though the load is varied? Give approximately constructive data of generator and motor. (The answer to the last question is optional).

9. You have to light a country house in which there will be 200 60-watt, 25 100-watt lamps and 4 9-ampere arcs. All the lamps may be required for five consecutive hours. A storage battery is to be used which must be capable of supplying the whole current required; the battery to be charged during the day, charging time five hours. Give size of dynamo and battery, and describe in general terms how you would arrange the installation?

Coast Communication: Tory Island.—The delay which has taken place in connecting by cable the lighthouse and signalling station on Tory Island with the Irish land lines is caused by the failure of negotiations between Lloyd's and the proprietor of the island for the purchase of the necessary land. Sir M. Hicks-Beach stated on Tuesday evening that probably Lloyd's would now proceed under the compulsory powers granted by the Act of last Session.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

"THE ELEKTROTECHNISCHE ZEITSCHRIFT" OF BERLIN.

"THE ELECTRICIAN" COMPANY *are also Agents for* "THE ELEKTROTECHNISCHE ZEITSCHRIFT" OF BERLIN, *published Fortnightly, and copies of this well-known Electrical Journal can be obtained at the Offices of* "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, E.C.,* **price 8d., post free, 10d.** *The Annual Subscription is* **£1. 2s. 6d.** *(post free),* PAYABLE IN ADVANCE.

Subscriptions are received by this Company for all Continental and American Electrical Journals. Subscription Rates on application to "THE PUBLISHER." *Remittance must accompany order* IN ALL CASES.

AMERICA AND SUBMARINE CABLES.

Our correspondent in New York and the technical journals of that city have lately announced some unusual activity in cable laying projects more or less directly connected with the United States; and we are asked to believe that much anxiety is felt in that country lest all the contracts for manufacturing the required cables should be, as usual, appropriated by British firms. Without attaching too much meaning to newspaper phrases, which may represent merely the disappointment of financiers, or possibly only the absence of something better to talk about, we can quite understand American electrical engineers being rather exercised in their minds in the face of opportunities such as those referred to, which occur but seldom, and which being missed are never likely to occur again. The matter is of no great importance to us, and British submarine cable manufacturers will look on with equanimity at any attempt on the part of America to compete with them in an industry which they have made peculiarly their own. To English electrical engineers generally, however, the subject is of some interest as showing that their own complaints—much exaggerated as we believe—against American competition find their counterpart on American soil, where we are roundly charged with greedily monopolising the cable trade of the whole world.

Digitized by Google

People seldom resent the language of envy, and probably the Americans are as indifferent to our complaints as we are to theirs when national aptitudes or fortunate accident has determined the home of a particular industry. When all the facts are known the explanation is not only simple but natural; and as regards submarine cable making and submarine cable laying we can confidently say that their nationality is far more easily explained than is that of some other important industries which continue to be peculiarly American. It was England that first wanted cables to connect her with the neighbouring shores of the European continent. She required them also as a link between herself and the Sister Isle, to say nothing of the less important fragments of the kingdom like the Isle of Wight—all of which afforded excellent means of testing the possibilities of submarine telegraphy. Gradually the operations were vastly extended, but always from our own shores; and by the time the demand for cables arose in other countries the manufacture was firmly established here. A seafaring nation naturally possesses great advantages in the operations of cable laying and repairing, and pre-eminence in this respect has doubtless contributed to our retaining the cable industry from beginning to end. Other causes, which we need not dwell upon here, have tended in the same direction; but, broadly, it is sufficient to say that nobody needed cables so much as we, nobody could make or lay them so well as we, and that, consequently, nobody else has found it worth while to compete with us.

The character of the industry is extremely technical, and has been built up by wide and varied experience among the very few firms who exclusively practise it in this country. And that those firms are so few is proof that their business is not lightly to be competed with. Enormous capital is embarked in these cables, and to sink it at the bottom of the sea without the guarantee of reputable and competent makers is not a proceeding which commends itself to capitalists of this country, and we should imagine not to those of America. The well-known English firms have since 1850 made and submerged almost every mile of telegraph cable that has so far been required, and it would surprise us, though it would not vex us in the least, if they do not for many years to come continue to command the confidence which their knowledge and enterprise have earned. Probably they are fully alive to the projects which are announced from the other side of the Atlantic. To say nothing of the Pacific cable which is yet in the embryo stage, there are the United States and Brazilian cable, a Chilian cable to the Straits of Magellan, a German cable to Portland, Maine, besides some Canadian cables, and the Halifax-Bermudas cable which has already fallen to an English firm. Of the rest, there seems still to be some uncertainty as to who will get the contracts; and the profits are supposed to be so attractive that electrical engineers in America are being spurred to stretch a hand for them or be branded as "unpatriotic" and spiritless idlers.

We have been unable to discover any better or more substantial reasons than these for the gratuitous advice offered by Mr. Herbert Laws Webb and other writers who talk fluently on the subject to American electricians. Perhaps we ought to except Mr. Webb's disparaging remarks about the Thames, which, as all the world knows, is less convenient for cable ships and cable factories than the docks of New York; and of course there are no docks in the Thames. But beyond these notable inducements which Mr. Webb calls facts, he has nothing to rely upon but the *amour propre* of his audience. They are "first in the universe" with all other branches of electrical engineering, and why should they lag behind England in the matter of deep-sea cable laying? "In a modest way" he points out that they could do as well as the Britishers if the Americans were not so shy about it; and unlike the man who was asked if he could play the fiddle, he answers, not that "he does not know, because he never tried," but that they only think they cannot do it because they will not try. Well, we have too much regard for our American friends to advise them or wish them to try, although we certainly should not begrudge them their well deserved reward if they succeeded. But they had better keep Mr. Webb's hand off the tenders. It will never do to set forth in black and white: "This is our first attempt; we want you to let us try what we can do; and if we can't secure the contract on these terms, we are prepared to lump down a heap of patriotism by way of guarantee." We repeat, this will not do at all.

REVIEWS.

Physical Memoirs, Selected and Translated from Foreign Sources under the direction of the Physical Society of London. Vol. I. Part I. (Messrs. Taylor and Francis, 1888.)

(Concluded from page 217.)

(SECOND NOTICE.)

Continuing our notice of Prof. Helmholtz's Paper on "Electric Boundary Layers," the author next considers the electrical phenomena arising from the flow of liquids past a solid wall, which is wetted by them. Prof. Quincke has investigated the E.M.F. produced by the motion of the liquid, and also the transfer of liquid produced by the passage of the current, and his results have been confirmed by the researches of J. Elster (Wiedemann's *Annalen*, Vol. VI., p. 553, 1879). The author explains these phenomena as follows:—"The liquid," he supposes, "stands in galvanic opposition to the walls of the tube, and the two build up an electric double layer along their bounding surface. The portion of this layer falling within the fluid is in general—omitting the exceptions pointed out by G. Quincke—positive. It is of extremely small though not of vanishing thickness. The side of this layer turned towards the bounding surface, at least in those cases in which the experimentally-found laws hold, clings immovably to the wall; the remainder can be displaced, subject however to the internal friction of the liquid. If an electric current be led through the liquid, producing a fall of potential, and therefore ponderomotive electric forces able to act on the electrically-charged parts, these forces drive along the positively-charged wall-layer of liquid. It results, however, from the internal friction of the liquid that the whole cross-section of the tube takes up the same state of motion if no hydraulic back-pressure prevent it. If there be any such, the motion of the liquid due to the pressure adds itself on to that produced by the forces of electric attraction. If the pressure drives just as much liquid backwards through any cross-section as the electric force drives forwards, a stationary condition of the liquid is set up in which the flow along the walls of the tube takes place in the direction of the electric force, but in the centre in that of the hydrostatic pressure. If, on the other hand, no external E.M.F. acts on the tube, but a hydrostatic pressure which propels primarily the water, then also the inner parts of the electrically-charged boundary layer of the liquid will be carried along at the same time. So long as this is displaced parallel to the wall of the tube with uniform velocity, and therefore remains continuously under the influence of the galvanic forces, its electrical equilibrium is not disturbed. Outside the exit end of the tube, however, it is either torn away from the wall by vortex motion, or, if it remain thereon, is forced into a thicker layer by the diminished stream velocity. By both processes its positive charge is liberated from the restraining influence of the negative layer on the wall, and becomes free. Conversely, at the beginning of the tube fresh layers are

Digitized by Google

approaching the wall, and since the latter already possesses a negative charge, the approaching liquid must withdraw from the rest its positive electricity, and leave negative therein. The negative electricity accumulated before the entrance of the tube, and the positive electricity collected beyond the end, compensate each other again, partly through the liquid column in the tube, partly through any other conducting path offered them. In such a conductor, therefore, a galvanic current will show itself. If there be no other conducting path, the potential difference between the ends of the tube must increase until as much electricity flows back by conduction along the tube as is driven forward with the water particles by convection. This explanation agrees in its essential outlines with that given by Professor Quincke. The author then goes on to consider mathematically the transport of fluid by the electric current, the rise of pressure due to electric diffusion, the transport of water by the discharges of Leyden jars, and the transport of electricity by a flowing liquid.

The rest of the Papers contained in the present number are devoted to the establishment, mathematically and experimentally, of certain thermo-dynamical theorems founded upon the second axiom of the mechanical theory of heat. In the experimental investigation it was necessary to find some chemical change capable of being applied in at least two ways to an exactly measurable and reversible production of work. This is possible in the case of change of concentration of a solution, and this change may be brought about by evaporation, by condensation of vapour, or by electrolysis. James Moser, in a series of investigations undertaken with a view of testing the author's theory, and described in Vols. III. and XIV. of Wiedemann's *Annalen*, has shown that the difference of E.M.F. in galvanic elements brought about by differences in the concentration of the salt solutions employed as electrolytes can be calculated thermodynamically from the vapour pressures of the solutions. The result, however, depends essentially on the velocity with which the electric transportation of the different constituents in the fluid proceeds. This introduces a considerable difficulty, as to calculate its effect on the result requires an elaborate series of measurements which have only been carried out in a few cases. The difficulty, however, may be eliminated by making use of galvanic elements with one fluid and an insoluble depolarising substance, such as those of Leclanché, Pincus, Warren de la Rue, Latimer Clarke, and others.

In his third Paper the author states that in writing the earlier Papers he had found that Lord Rayleigh, in a lecture delivered at the Royal Institution on March 5th, 1875, laid down for the first time the general principle that the evolution of heat alone is not conclusive as to a possibility of a chemical change taking place in a given direction, but that change can occur only in the case in which the entropy, or dissipation of energy, increases, or at any rate does not diminish. F. Braun, in 1878, had already pointed out, and demonstrated experimentally, that the development of heat taken by itself is not sufficient to determine the magnitude of the E.M.F. of a cell. The author mentions that the great simplification produced in the thermodynamic laws by expressing the energy and entropy of a system as differential coefficients of an integral function was discovered before him by F. Massieu, in 1887 (Wiedemann's *Annalen*, Vols. V., XVI., and XVII.), and completely expressed, at any rate for two variables, though without reference to chemical processes. He also alludes to J. Willard Gibbs' important Paper on "The Equilibrium of Heterogeneous Substances" (American *Journal of Science*, Vol. XVI., 1878), in which the thermo-dynamical conditions of molecular and chemical processes in systems of bodies, consisting of mixtures of compounds of any number of different substances, have been analytically developed in a very comprehensive and general manner. These deductions from thermodynamics are of special importance for the theory of galvanic polarisation, since it is clear that the excess of the free energy of the mixed electrolytic gases above that of water depends to a great extent on the pressure, while the development of heat during their combination is nearly independent of it. So long as it was supposed that the E.M.F. of polarisation was to be deduced from the heat evolved (as the author himself had done in his earlier Papers) the E.M.F. had to be looked upon as very nearly constant, which made certain phenomena of the polarisation of a voltameter almost inexplicable, but if it be deduced from the free energy, it is obviously variable in the highest degree according to the saturation with gas of the liquid layers which lie close to the electrodes. Thus the explanation of a great part of the phenomena of polarisation is modified and most of what was before unintelligible is now made clear.

As the author's attempts to explain the processes going on in galvanic polarisation are scattered through a long series of Papers, and some of them require modification to bring them into agreement with his present point of view, he recapitulates the chief points, and we cannot do better in view of its value and importance than to reproduce this recapitulation in the author's words: "The fundamental assumptions," he says, "from which I have always started are the law of the conservation of energy and the rigid applicability of Faraday's law of electrolysis. In accordance with the latter I maintain that electricity can pass from the liquid to the electrodes only on the condition that an equivalent amount of chemical decomposition occurs, and that unless the work necessary for the dissociation of the chemical compound can be supplied by the electric forces present, this transfer cannot take place, but the bounding surface acts like a layer of perfectly insulating material.

"If the two electrodes of a voltameter be charged and maintained at different potentials, electric forces corresponding to the slope of potential act within the fluid driving $+E$ to the cathode, $-E$ to the anode. This movement of electricity never takes place so far as we know without a simultaneous motion of the ions of the electrolyte, to which the $+E$ and $-E$ set in motion are attached. Positively-charged hydrogen ($H+$, $H+$) passes, therefore, to the negatively-charged cathode, and negatively-charged oxygen ($-O-$) to the positively charged anode. If subsequently evolution of gas takes place, the gases evolved are electrically neutral. Accordingly, if the principle of Faraday's law be consistently applied to this instance the evolved hydrogen must be ($H+$, $H-$), and the liberated oxygen must either be ($-O-$, $+O+$), or ($-O+$). Since the molecule of evolved oxygen consists of either two or (ozone) three atoms, I consider the first form the more probable. Ozone would be ($-O-$, $+O-$, $+O+$). The accumulation thus produced of ($H+$) at the negatively-charged cathode and of ($-O-$) at the positively-charged anode is indicated by the "condensation current" which enters the electrodes while undergoing polarisation. In this case the two electrode surfaces behave like two condenser plates of enormous capacity, owing to the extraordinarily small, *i.e.*, only molecular, distance apart of the oppositely-charged layers. If after removing the battery the two electrodes are joined by a simple conducting wire, the two condensers are discharged back through the wire, thus giving the depolarising current. To the electrical movement thus set up, which does not extend beyond the boundary of the liquid conductor, the chemical forces within the liquid appear to offer no resistance, since under the influence of electromotive forces electrolytic conductors assume a condition of electrostatic equilibrium quite as completely as metals. This is proved to a high degree of accuracy by Sir W. Thomson's water-dropping collector, in which the weakest E.M.F.s are able to charge the separating water-drops to a condition of perfect electrostatic equilibrium. In decomposing cells, freed as completely as possible from air, I have myself succeeded in following out the proportionality between the E.M.F. and the amount of condensed charge—a proportion easily demonstrated for very small E.M.F.s—down to E.M.F.s of 0·0001 Daniell. On the other hand, the transfer of electricity from the charged ions of the boundary layer to the metal obviously takes place subject to the resistance of the chemical forces. It is the electrical discharging of the ions which definitely ruptures the chemical combination; so long as they are not discharged they can still return from the accumulated mass of atoms in the boundary layer, and assume their previous state of combination without any evolution of heat taking place, provided that the diminution in the electrical attractions which retain them at the electrodes be slow. This leads to the conclusion that the greatest and most essential part of chemical force, that, namely, which holds together really typical com-

Digitized by Google

pounds, is based on the different attractions of elementary substances for the two electricities. Faraday's law compels us therefore to assume that each valency of every element is always charged with one whole equivalent either of positive or of negative electricity, and that the magnitude of these equivalents of electricity is independent of the nature of the substance to which they are attached, just as the atomic weights of the several elements are independent of the combinations into which they enter; just as if electricity were itself divided into atoms. That the electric forces which we have here to consider are not by any means too small to yield the great quantities of work evolved in chemical separations and re-combinations is obvious, if the enormous amount of equivalents of electricity accumulated by this process be considered. My calculation given in the Faraday lecture proves that if the +E attached to the atoms of a milligramme of water could be transferred without loss to a sphere, and the −E to another sphere at a distance of one kilometre, the two spheres would attract each other with a force equal to a weight of 26,800 kilogrammes. It is precisely in consequence of the enormous magnitude of these atomic charges that the relatively weak forces of attraction which one or two Daniell's cells can exert are competent to produce so comparatively large an amount of work. These forces are weak only in relation to the small quantities of free electricity yielded by our electrical machines. The formation of the electric double layers necessary for the setting up of electrical equilibrium explains a large and important part of the process going on in polarisation, viz., the strong initial current during the charge and discharge of the electrodes. These currents can be made of sensibly greater duration if simultaneous occlusion of one or both gases in the metal of the electrodes takes place. But neither of these two processes explains the unlimited duration of the current with feeble E.M.F.s. In my Paper of the year 1873 I showed that the gases, especially atmospheric oxygen, dissolved in the liquid electrolyte, exert the very greatest influence on the strength of the continuous current, and I explained the origin of the currents depending thereon, viz., the convection currents. In this case we have to bear in mind that electrically neutral gases dissolved in the liquid are not subject to the action of the charged electrodes in the same way as the charged ions before their discharge, but can diffuse freely through the liquid. If we now assume a stronger attraction on the part of oxygen for negative electricity, neutral oxygen in solution will be able to saturate itself with −E at the negatively-charged cathode without resistance, or may even [in doing so] contribute positive work towards the maintenance of the current, and may then either unite with (H+. H+) or set out on a new migration towards the anode, while at the same time a molecule of (−O−) becomes neutral at the anode. The whole work done by the battery consists then only in this: that neutral oxygen dissolved at the cathode in a part of the liquid poor in oxygen disappears as such, takes up a negative charge, and becomes a constituent of water, while at the anode the anion of water becomes neutral dissolved oxygen, but passes into a part of the liquid rich in oxygen. A stationary current is possible so long as the same quantity of dissolved oxygen is brought back by diffusion from the anode to the cathode as is carried as anion by the current from the cathode to the anode."

The author affirms that we may always convince ourselves that it is impossible for the fluid to attain a condition such that a galvanometer would not show a continuous current for an E.MF. less than that of a single Daniell. The galvanometer employed by the author gave a deflection of the scale-division for a current strength of 10·9 ampere, a current which would require 334 years to decompose 1 milligram of water, and if only 1 cubic centimetre (0·0005 millimetre) of oxyhydrogen gas at 0·760 millimetre were dissolved in the water, its constituents would have only to migrate once in 36 days from the anode to the cathode in order to give the observed current. Similarly, it became evident that even in cells freed as completely as possible from air, the polarisation had not reached its highest limit when the evolution of bubbles of gas began, and when, therefore, the E.M.F. of the battery had become great enough to overcome the resistance of the chemical forces. The counter-E.M.F. of polarisation, on the other hand, always increased with the E.M.F. of the polarising battery, even though the gas had been briskly evolved for some time. The author states also that for values of the E.M.F. which lie near to the limiting value corresponding to evolution of gas nothing in the behaviour of the current is observed which would suggest any sudden overpowering of the chemical forces by the E.M.F. The thermodynamical theory, he points out, offers a satisfactory way out of this difficulty, for it shows that if the gases formed are dissolved in the liquid electrolyte, the resistance due to the chemical forces which the current has to overcome must become continually greater and greater as more of the evolved gas enters into the solution round about the electrodes, and that the part contributed by the gas to this resistance is by no means inconsiderable, but may attain any conceivable value between 0 and ∞.

In the last Paper, viz., No. 5, the author points out that the investigations contained in the three Papers on "The Thermo-Dynamics of Chemical Processes" lead to the result, important for the doctrine of polarisation, that electrolytic decomposition of water can be brought about by E.M.F.s which may be smaller the smaller the quantities of hydrogen and oxygen that exist dissolved in the neighbourhood of the electrodes, so that, in fact, no other limit than zero can be assigned for the smallest E.M.F. capable of decomposing water that is perfectly free from gas. At the same time he observes that the quantities of explosive gas evolved for E.M.F.s which amount to less than 1·5 volt are so extraordinarily small that they can be perceived in no other way than by the weak residual currents which they maintain. Moreover, he showed previously that in water which originally was completely free from gases even the weakest E.M.F. is capable of maintaining a permanent electric current through the liquid; for the smallest quantity of gas which at the electrodes has become free and electrically neutral will penetrate little by little by the process of diffusion to the opposite electrode, and will thereby set free a fresh quantity of a polarising current in the direction of the battery current. Chemically recognisable quantities of dissolved oxygen and hydrogen must act incomparably more strongly. The rest of the Paper is mainly devoted to the experimental determination of the minimum limits of E.M.F. required to develop fresh gas under a given pressure of oxyhydrogen gas upon the liquid.

THE ELECTRIC LIGHTING OF THE PARIS BOULEVARDS.*

The rapidity with which the electric lighting of the Paris Boulevards was carried out, involving, as the work did, the construction of a complete system of subways and conduits and the laying of several miles of underground mains, was due to the

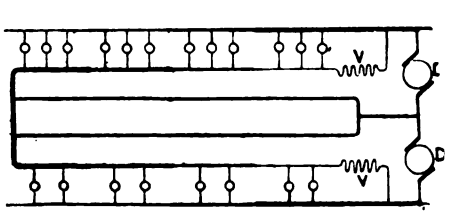

Fig. 1.

fact that the contracting companies had their plans already prepared and their central stations already in operation. Had this not been the case it is possible that even now the light would not have been available. The three companies undertaking the work are the Compagnie Edison, the Compagnie pour la Transmission de la Force par l'Électricité, and the Compagnie Française de l'Air Comprimé.

The Compagnie Edison have the lighting of the Grands Boulevards from the Porte St. Denis to the Opera House, and they have put up 34 10-ampere improved Pilsen arc

* Abstracted from *La Lumiere Électrique.*

Digitized by Google

lamps, which are mounted on handsome bronze posts seven metres high. Of these lamps 30 are placed in the middle of the roadway, and four are grouped together on a refuge in front of the Opera House. The lamps are all arranged two in series across the mains. The current is supplied from the recently acquired station in the Rue du Faubourg-Montmartre. This station when complete will have a capacity equal to 13,000

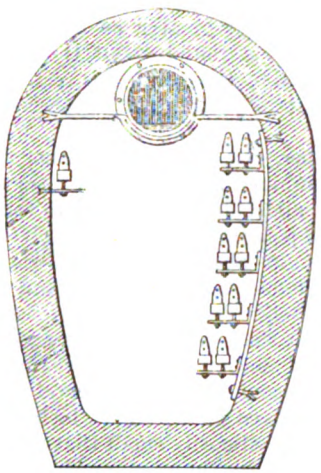

Fig. 2.—Cross-section.

16 candle-power lamps. The distribution is on the three-wire system, but in lieu of feeders the arrangement shown in Fig. 1 has been adopted. It will be seen by the diagram that the cross-section of the mains diminishes on one side of the lamps and increases on the other in such a way as to keep the total

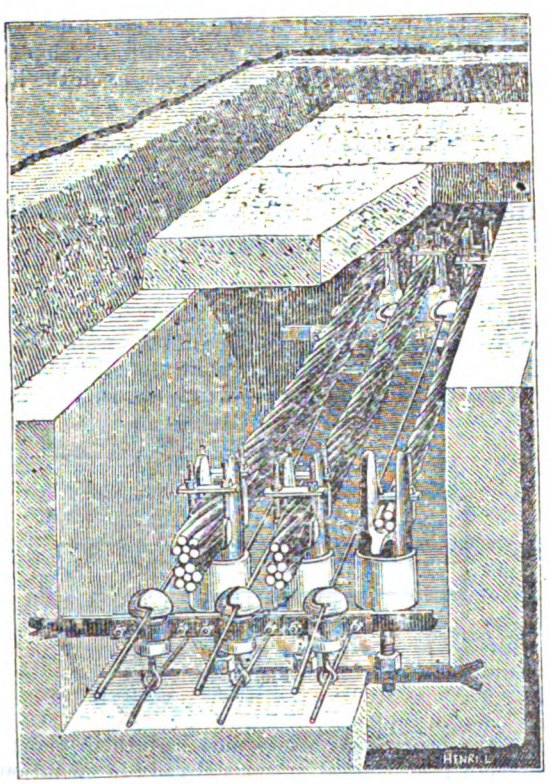

Fig. 3.—Perspective View of Condu under the Pavement.

cross-section always the same. The cables, which are of silicium bronze, are taken across the roadway in subways (Fig. 2) and along underneath the kerb in conduits (Fig. 3). In the subways the cables are run on insulators supported on cast-iron brackets fixed to the side of the subway. The conduits are of concrete, covered in by slabs of the same material, the top being about 15 centimetres beneath the asphalt. The cables are run through iron clips fixed to porcelain insulators, which are secured to transverse iron bars laid in the bed of the conduit. These supports occur at every two metres. Of the small wires shown in Fig. 3, some are used in connection with the tension indicators and some to carry the current actuating the clockwork of the subscribers' meters, while others are used for purposes of telephonic communication. The subways are connected to the conduits as shown in Fig. 4. The conduits are 37 × 55 centimetres, and the subways are in most cases 1·5 metres high and ·75 metres in breadth. At present there are five circuits running from the station in the Rue du Faubourg-Montmartre, two of which run along the Boulevards to supply the public lamps.

The Société pour la Transmission de la Force have 27 10-ampere lamps running from the Place de la Republique to the Porte St. Denis, these lamps are mounted and arranged two in series across the mains, similarly to those of the Compagnie Edison. The Compagnie Française have put up 37 Thomson-Houston arc lamps—8 on the Place de l'Opera, 10 along the Boulevard des Capucines, 5 on the Place de la Madeleine, and 14 in the Rue Royale. The mains are all run underground in iron pipes, ·2 metres in diameter, the cables being drawn in by means of openings placed 50 metres apart.

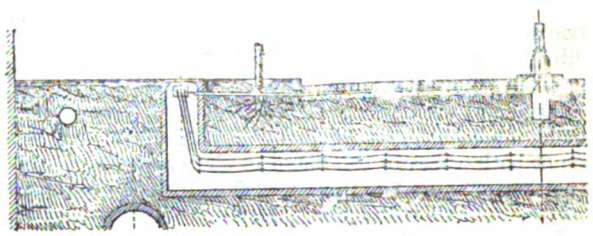

Fig. 4.—Subway under the Boulevard des Capucines.

The electric lighting of the Boulevards affords the public an excellent opportunity of seeing several systems at work side by side, and it is hoped that when the present contract terminates, which it does on the 1st November, the authorities will definitely adopt the most satisfactory of the three systems.

PROBLEMS IN ELECTRIC TRACTION.*

BY DR. LOUIS BELL.

(Concluded from page 227.)

The next experiments were to determine the losses on the line. These were found from observations of the fall of potential between power station and cars, taken both on regular and special trips. The efficiency of the line is a constantly-varying quantity, changing, of course, with the position and ohmic resistance of the motors. A general average along the line showed an efficiency of 90—95 per cent.

Attention was next turned to the speed and efficiency of the motors. The observations were confined to a single car, No. 106, which was a good average car in its general performance. As a preliminary the resistance of the motors and connections was measured with a switch in each successive step. These resistances measured cold were :—

Step.	R.	Step.	R.
1	10·76	5	2·83
2	6·98	6	2·83
3	6·98	7	2·17
4	5·44		

The resistance of an armature cold was 1·2 ohms, measured from brush to brush.

Two spaces each of $\frac{1}{10}$ mile were then measured off, one on a level, the other on a grade of 6·58 per cent. average. Experimental runs were then made with car No. 106, carrying 19 persons and instruments. The total weight of car and contents was 8,200lb. The runs were made in each case with a flying start, each step of the switch being separately tested.

* From the *Electrical World* of New York.

Digitized by Google

The results of an experiment on the level were as follows :—

Step.	Miles per hour.	Volts.	Amperes.	E.H.P.
1	7·5	404	9·5	5·15
2	9·3	416	10·4	5·79
4	9·1	393	10·7	5·64
5	10·9	434	16·1	9·35
7	12·4	433	15·4	8·93

The somewhat anomalous result in step 4 is due to the very considerable drop in voltage.

From these experiments the efficiency of the motors may be deduced, and since the motors are geared down very nearly twelve times, the armature speed can also be obtained. In computing the electrical efficiency of the motors, allowance must, of course, be made for increase of ohmic resistance due to heating, for self-induction, hysteresis, &c. Following Mr. Sprague's own figures, I have allowed 10 per cent. increase in resistance by heating. It is my firm conviction that this, under favourable conditions, will more than cover the above losses. Nevertheless the loss due to hysteresis must be quite considerable. Computing this by Hopkinson's method for an approximate size of core, and an armature speed of 1,200 revolutions per minute, it appears that the energy spent in hysteresis may amount to somewhere about 500 watts. The loss of energy due to sparking may also rise frequently to a quite perceptible amount.

Computing then the electrical efficiencies under the various conditions we have the following results :—

Step.	Armature speed.	E.H.P.	Motor E. H. P.	$\frac{C\,e}{C\,E}$ Per cent.
1	1,000	5·15	3·72	72·3
2	1,230	5·79	4·67	80·7
4	1,200	5·64	4·74	84·2
5	1,450	9·35	8·29	88·7
7	1,650	8·93	8·18	91·5

Unfortunately a car motor does not lend itself at all readily to brake tests, the conditions of such a test being widely different from those under which the motor works. We can, however, obtain an approximation to the commercial efficiency by computing as nearly as practicable the coefficient of friction on track, and then applying this to the data obtained on a known grade to estimate the work actually done.

Assuming, then, a loss of 10 per cent. in friction of motors and gearing, in accordance with Mr. Sprague's own estimate, and using the data above, the coefficient of friction appears to be 2 per cent. ; in other words, 40 lbs. per ton. This is a high value, but, I think, justified by the condition of the track.

Substituting this constant in the formula used with the results of the grade test we can obtain a close approximation to the commercial efficiency, and a check on the above estimate of 10 per cent. friction.

The grade tests were with the same car and load. The results were as follows :—

Step.	Miles. per hour.	Volts.	Amperes.	E. H. P.
2	2·73	347	27·2	12·65
4	4·2	403	27·4	13·47
5	9·3	409	31·3	17·14
7	6·2	355	32·4	15·85

The general voltage here was rather low, produced in part by the location of the grade relative to the power station, and mainly to heavy demands for current during the test. It serves to emphasise what I have previously mentioned, the advantage of using compound-wound dynamos on tramway work.

Computing now the electrical efficiency by means of the above data—

Step.	Armature speed.	E.H.P.	Motor. E.H.P.	$\frac{C\,e}{C\,E}$
2	333	12·65	5·06	39·9 per cent.
4	545	13·47	7·98	59·3 „
5	840	17·14	13·04	76·1 „
7	830	15·85	12·50	78·9 „

Step 1 was not tried on the hill on account of endangering the field coils. Notice, for example, that in case of step 2 there is 7·59 estimated horse-power spent on internal work. No coil can stand such treatment for any length of time, and with this light it is quite easy to see why fields and armatures burn out. On a grade like this, nothing short of full power should ever be used.

Compute now the actual work done by the motors on this grade, using the above data and the friction coefficient previously found. We have then virtually the brake horse-power, and hence the commercial efficiency $\frac{B.H.P.}{E.H.P.}$.

Step.	M.E.H.P. 10 per cent.	B.H.P.	$\frac{B.H.P.}{E.H.P.}$
2	4·56	4·67	36·9 per cent.
4	7·19	7·65	56·9 „
5	11·74	11·80	67·6 „
7	11·35	11·61	73·2 „

The agreement between the second and third columns shows that the estimate of 10 per cent. for friction of motors and gears was substantially correct. A second approximation could, of course, be deduced. It appears, therefore, that the motors with their gears may reach an efficiency of over 80 per cent. on the level, or over 70 per cent. on a severe grade when used under favourable conditions. When used with the lower steps of the switch the resistance of the field coils is so high as to reduce the efficiency enormously. In other words, when the cars run slowly they do so at the expense of greatly diminished efficiency. Still, less power is used, and if the field coils are well insulated, the lowest step of the switch sufficient to give the required speed will be the most economical one. On grades, however, the fifth or seventh step should be always used to avoid excessive heating. The very high ohmic resistance of these motors is a source of continual loss, as has been pointed out in detail by Mr. Snell (*The Electrician*, Vol. XXI., p. 522), and is the cause of unnecessarily great destruction of field coils. It may be possible to so insulate the coils as to withstand the roasting to which they are too often subjected, but this is a questionable way out of the difficulty. From observations on the cars during regular trips, the average electrical efficiency in ordinary use appears to be about 75 per cent., and the commercial efficiency of motors and gearing 65 to 70 per cent. We are now in a position to obtain the approximate efficiency of the entire system $\frac{B.H.P.}{I.H.P.}$. The mean value for this line as at present worked is about 25 per cent. The chief cause of this low efficiency has been already pointed out. The figure will probably be considerably increased before long by the increasing use of stationary motors, which will raise the mean electrical output to something like the proper figure. As a system increases in size the efficiency will rise, and in a system as large as that at Richmond the total mean efficiency would appear from the data obtainable to be a little over 40 per cent. This may seem a low figure, but it should be remembered that traction work is probably the least favourable to high efficiency of any task to which an electric motor can be put. Most of the losses incurred are unavoidable ; engines will not run without friction, dynamos are not of ideal efficiency, line wire will have resistance, an electrical current will generate heat in the motors and gears will grind and wear. Losses like these cannot be avoided or reduced below certain limits. These limits are not easy to set, but one can safely say that a total mean efficiency, $\frac{B.H.P.}{I.H.P.}$, of anything over 50 per cent. would be a very remarkable performance for a traction system in actual use. I do not think that 60 per cent. is likely to be reached without very radical improvements. This applies of course to the direct supply systems.

The storage battery requires a separate investigation. In that case the power stations can be worked to rather greater advantage than with direct supply, since the load can be made much more regular. There is no loss by the wire but there is a very serious loss in the accumulators themselves. The laboratory efficiencies of storage batteries rise to a most tempting amount, 80 per cent. and over, but the irregular discharge rate necessary in operating a tramway is even more disastrous to the efficiency of a storage battery than to the efficiency of an engine. With any accumulator now made, a mean efficiency of over 65 per cent. is doubtful under the conditions which exist in tramway work. There is great need of careful tests under something like working conditions, but so far as I am aware none have been published, at least none of any scientific definiteness. I may here remark, that, with very few exceptions, the reports published on electrical traction work are models of how to avoid giving definite information. Perhaps the most serious charge against the accumulator is its very great weight. It appears to require about thirty-five hundred pounds of battery to operate a car successfully, and this amount must be carried as well as

Digitized by Google

the passengers. Of the total electrical output then something like 25 per cent. is employed in dragging around this dead weight. But this is not all. Sit down with a list of storage batteries and compute the weight required to furnish the car, say, 10 estimated horse-power. The fact at once appears that if we undertake to supply from storage batteries the same amount of power we supply from a line, we shall need something like twice the above weight of storage battery. In short, the weight of battery is reduced by reducing the supply of power. Nevertheless, the storage system is deserving of consideration. Each car is a unit, there are no conduits or overhead wires, there is lessened danger of breakdowns, and independence generally. If the storage battery comes to be of reasonable durability and weight, it will furnish an ideal solution of the tramway problem, particularly for city work where overhead wires are a nuisance and conduits are troublesome. Given a mean efficiency of 60 to 70 per cent. for the accumulators, it is easy to form a pretty clear idea of the total mean efficiency of the storage system. The power station will be somewhat more efficient than with direct supply, $\frac{\text{E.H.P.}}{\text{I.H.P.}}$ being perhaps 80 per cent.; the batteries will be of, say, 65 per cent. efficiency, and finally the motors will be about as before, giving a total efficiency of a little less than 40 per cent. In practice this is diminished by the fact that for the same service the storage system car would require from a fourth to a third more power on account of its constant load of battery. So far as efficiency is concerned, there seems to be little prospect of the storage system equalling direct supply, since the loss on the line is so small compared with that in the battery.

Probably the most effective rival of electricity is the cable traction system, and it is well to look into its efficiency a little. Facts are not particularly easy to get at. Some of the theoretical discussions of transmission by wire rope give a preposterously high efficiency. A valuable Paper, however, in the Journal of the Association of Engineering Societies, September, 1888, gives some interesting and authentic figures as to efficiency, details of construction and cost. The St. Louis and Western cable road, having a cable in one piece, 34,600 feet long, required 185 horse power to drive the empty cable at the rate of eight miles per hour. Regular capacity of the road 40 cars (20 trains of grip and car). Under ordinary conditions of traffic 180 to 190 horse-power additional was required to operate these cars, 9—9·5 horse-power per train. Curves are numerous on the road. The Fifth-street road, Kansas City, operates 40,000 feet of cable. The conditions of working are better than at St. Louis, there being few curves. Twenty trains are operated, taking under usual conditions 280 indicated horse-power, 120 of which is required to drive the cables at the rate of eight miles per hour, leaving 8 horse-power per train as the power required. In these roads, then, 50 to 60 per cent. of the indicated horse-power seems to be applied to doing useful work.

It is instructive to compare this performance with that of the Richmond electric road, which operates single and double track, covering 8·8 miles of streets, and 40 cars aggregating almost exactly the same weight and seating capacity as the above 20 trains. The mean electrical output at the power station is per car 4·5 estimated horse-power. Making due allowance for loss in the power-station, it appears that the total power required to operate the system is about the same as in the Kansas City cable line, and distinctly less than in the St. Louis cable. The curves and grades in Richmond are more severe than in the Kansas City line.

We may conclude then that in the case of good-sized systems the power required to operate is nearly the same with cables and electricity; the former having the advantage on short and easy lines, the latter on long and difficult ones. On smaller systems electricity has a decided advantage, since the loss of power in the motors depends on their number, while the loss in dragging a cable is constant.

But there is another side to this comparison, the economic one. A cable road costs $50,000 to $75,000 per mile, owing to the large and complicated sub-structure. This does not include power stations or rolling stock. This cost is four or five times greater than for an electric overhead road, even under unfavourable conditions, and something like twice as great as for an electrical conduit system. This comparison supposes the electric road to be laid and wired in the most efficient and permanent way. Under ordinary circumstances the difference in first cost would be even greater. The difference in running expense is not so easy to estimate. Not far from the same amount of power is required, though it is probably procured at rather less expense of coal in the cable system. The number of *employés* cannot be widely different, the difference being of little moment. The cable conduit, however, requires decidedly more care than the electric line, supposing the latter to have been properly put up in the first place.

As to repairs, on an electric system using overhead wires, the line if properly put up and occasionally aligned should give very little trouble. The trolley of whatever description is subject to constant wear and must frequently be renewed or repaired, and the brushes rapidly wear out. On some lines the wear of brushes amounts to almost a set per week per car. There is great chance for improvement here. The field coils now and then burn out, in some cases frequently, and occasionally an armature is damaged. On a cable line the cable itself is a considerable item of expense. Its life may be from six to eighteen months, though occasionally only a few weeks; and the expense of renewal is considerable. The grips are subject to continual wear, the dies that form the jaws generally lasting only a week or ten days. The running gear along the line requires constant watchfulness and attention, and the minor repairs on this must be considerable. As regards the comparison of actual operating expenses, it is almost impossible to get definite information. Both cables and electricity are distinctly cheaper than horses. Reports from the Chicago cable roads indicate expenses about 50 per cent. of the cost of operating by horses. From this the figure may rise to 75 per cent. Reports of anything like a definite kind from electric roads are scarce. Such scattered figures as can be collected tend to show that the operating expenses are about the same as for cables on systems of the same size. Details of operation vary so much from place to place that it would at present be unjustifiable to say more than this. The detailed reports from electric roads have for the most part been from very small ones. A recent one from the Devonport, Ia., road shows expenses 97 per cent. of those with horses the previous year, and net profit three times as great. This road operates only four regular cars. One or two small English roads report something of the same kind, slightly diminished expenditures and greatly increased receipts.

In closing it seems worth while to say a word about the use of electricity for ordinary railroad work. In elevated roads there can be little question about the matter; the smoke and dust of the locomotive are quite enough to condemn it, and as the consumption of coal is over 6lb. per horse-power hour, an electric system can push it hard in the matter of economy. In ordinary cases, however, there is no call for sacrificing economy for the sake of the characteristic advantages of an electric system. It is quite possible for a locomotive to give the horse-power hour on 4lbs. of coal, a figure which can probably be reduced. This leaves no very large margin for the double transformation of an electric system. In fact, so long as we have to depend on the steam-engine and dynamo for our supply of electricity, competition with the direct use of steam in locomotives will be hopeless. Even water-power will not be of much avail, and the longer the line to be operated the less chance of success. If we could get electricity directly from heat in any economical way the problem of power would be solved.

Finally, with regard to electric traction systems, most lines of road are not laid and wired with sufficient care, and most of the minor difficulties in operating come from this fact. A line with track hastily and imperfectly laid, with wiring carelessly put up on rickety poles, and imperfectly aligned, will surely encounter plenty of small but exasperating difficulties and bills for repairs that will be anything but pleasant. A vigilant system of car and line inspection will avoid most of the little accidents that interrupt traffic, and will more than pay for itself in lessened repairs. With a carefully-constructed line and a properly-designed power plant, electric traction becomes thoroughly reliable and remarkably economical. Without these it may be very uncertain in its operation, and while it will nearly always pay, the size of the dividends will not be pleasant to contemplate. If much power is to be used for stationary motors, it is better and in the long run cheaper to divide the plant than to rely entirely upon a single engine.

I cannot close this Paper without expressing my obligation to Mr. Hawter, superintendent of the road, who has facilitated this investigation in every way possible, and to Messrs. F. W. Brady and W. J. Lutz, post-graduate students in this university, for most efficient aid throughout the tests.

"THE SPECIFIC RESISTANCE AND OTHER PROPERTIES OF SULPHUR."*

BY JAMES MONCKMAN, D.SC.

Resistance.

It is well known that sulphur in a solid state insulates electricity of very high potential, and conducts heat badly; also that it undergoes a curious series of changes when heated—melting at about 120deg. C., becoming thicker at 200deg. to 250deg., more liquid at 250deg. to 300deg., and boiling under atmospheric pressure at 440deg. During the past three terms I have been engaged in the Cavendish Laboratory in trying to determine whether these changes

* The above article contains the substance of two recent communications to the Royal Society, but the author has kindly rearranged the material for this journal, so as to obviate the necessity of repetition.—Ed. *E.*

Digitized by Google

are accompanied by corresponding ones in the electrical resistance and other properties of the element.

I expected that the changes would be within the limits of an insulating body, hence my first experiment was designed to test the insulating power for frictional electricity.

Two platinum wires were placed in a beaker of melted sulphur at a distance of about 1 centimetre apart, one being connected to an electroscope, the other going to earth. When the sulphur became solid the leaves of the electroscope remained open on charging for a considerable time, but fell at once if any portion of the sulphur between the wires was liquid. To avoid all discharging by the flame used in melting the sulphur, the platinum wires were fixed to an ebonite rod at the proper distance apart. After melting the sulphur the flame was removed to a distance and the wires placed in the liquid. The discharge was complete and, apparently, as sudden as when contact was made with a wire.

The same experiment was tried with paraffin, and the discharge found to be very slow.

Seeing then that the resistance was removed by melting the sulphur into the region of conductors, it became necessary to find some method that could be used for conductors of very high resistance.

At Mr. Glazebrook's suggestion, I tried placing the wires in melted sulphur in circuit with a high-resistance reflecting galvanometer and a set of accumulators giving a total electromotive force of 60 volts. With platinum wires in the sulphur no reliable results could be obtained, as the current quickly fell away.

Having some graphite rods which had been procured from Hogarth and Hayes, Keswick, for some experiments on carbon, I

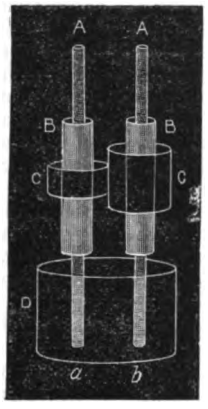

FIG. 1.

tried two of them, and obtained a perfectly constant flow of electricity, even at the boiling point. The change in the resistance between melting point and boiling point was so great that it was difficult to arrange a method that would give reliable readings. In the Cavendish Laboratory, where this work was done, we have a set of 26 accumulator cells, which when charged give a potential of about 60 volts. This is conducted to all the rooms, and is so arranged that we can use any number of cells, so that we can vary the potential from 60 volts to about 2½ volts.

When the sulphur was melted (125deg. C.) 60 volts gave a deflection with a reflecting galvanometer of 11,770 ohms resistance of only half a millimetre on the scale, while at 440deg. C. one cell gave a deflection of 60 millimetres.

By changing the number of cells, and measuring the potential by a Thomson's graded voltmeter at each change, the results given in the following tables were obtained.

The graphite rods were carefully insulated from each other by hard glass tubes, over which shorter pieces of tube of unequal length were placed, and fixed with plaster of Paris, the object being to give as much insulating surface as possible. A cell of mica was placed around the projecting part of the graphite rods to render the path of the current fairly parallel; the ends were left open to allow free access of sulphur, and to prevent vapour taking the place of the liquid when ebullition commenced.

The form of the mica cell was preserved by an outer cell of thin glass.

In Fig. 1, A, A are the graphite rods, B, B glass tubes, C, C larger ones, D mica. The exposed ends were filed flat, and fit loosely into the tube D. The dimensions are—length, 30 millimetres; width, 3⅜ millimetres; distance, 7 millimetres between the free ends *a b*.

The change of resistance was so great and fell so quickly at the higher temperatures that it gave rise to a suspicion that the increase of conductivity might arise from particles of the rods being torn off and mixed with the sulphur. To test this, the rods were placed in a second tube of boiling sulphur, so that when placed in the tube of pure sulphur they might not reduce the temperature of the liquid. After removing and allowing the adhering liquid to flow back, they were placed in the other vessel, and the current passed at once. The deflection was the same as before, and steady, neither did the rods appear to be acted upon in any way.

Hence we concluded that the change was in the sulphur itself.

RESISTANCE.

Ordinary Roll Brimstone.

Temperature.	Potential.	Deflection.	Reduced to one standard by multiplying by 60/*v*.
440°	2⅛	60	1560
300	,,	12·5	325
270	,,	2	52
250	,,	1	26
250	55	10	24
223	...	3	7
195	60	6	6
150	,,	5	5
140	,,	2	2
125	,,	0·5	0·5

Another specimen gave slightly different numbers, but of the same order.

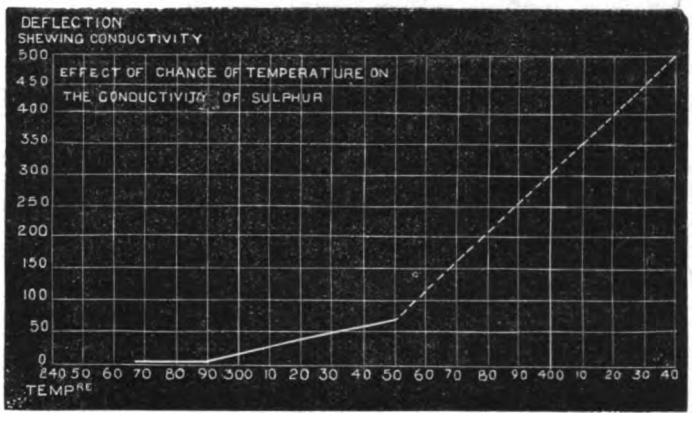

FIG. 2.

With precipitated sulphur the resistance was considerably higher.

Precipitated Sulphur.

Temperature.	Potential.	Deflection.	Reduced to one Standard by multiplying by 60/*v*.
440°	4·1	35	512
350	,,	5	73
335	...	3	44
335	8·2	7	51
290	54	5	5·5
280	,,	2·5	2·8
260	,,	0·5	0·55
125	...	Could get up a swing only.	...

The accompanying curve (Fig. 2) shows the conductivity of precipitated sulphur. At 290deg. C. there appears a sharp bend in the line. Up to that point the conductivity rises to 5·5, becoming 51 in the next 45deg., after which it rises rapidly. This bend coincides fairly with the second fluid state, and probably indicates some molecular change which appears to produce similar irregularities in its other properties.

As there was some doubt whether the impurities in ordinary sulphur and in precipitated sulphur did not produce the changes mentioned, great care was taken to prepare pure sulphur. Three methods of purification were used, and these so differed among themselves that if by any means any foreign body escaped removal they would differ in each specimen, and hence cause variations that would certainly lead to the detection of the intruder.

These methods may be indicated shortly, to give some idea of the work and avoid being tedious. First, solution in bisulphide of carbon, crystallisation from the solution, distillation in vacuo; second, distillation in sulphur chloride vapour, and then in vacuo;

Digitized by Google

third, precipitation of sulphur from a solution of hyposulphate of soda by means of hydrochloric acid, and distillation first in air then in vacuo. This distillation was repeated many times, and only the middle portion retained.

In making the measurements very great difficulty was experienced at first in avoiding chemical action between the boiling sulphur and the electrodes, and even the glass vessel containing the liquid.

This was satisfactorily managed by using combustion tubing, protected from the direct flame, for the boiling vessel, and electrodes of thick platinum wires.

When a reading was taken the wires were immersed in the liquid and withdrawn as soon as the experiment was finished, so that the metal was exposed to the boiling liquid for a short time only, and chemical action thus avoided.

The specific resistance calculated from these three specimens is

7·7 meghoms at boiling point, or 440° C.
56·5 ,, ,, 350° C.
282·5 ,, ,, 300° C.

While precipitated sulphur gave 5·6 megohms at 440° C, at 350° C and 300° C it gave the same as pure sulphur. Roll sulphur at 440° C was 1·66 megohms.

Other experiments in the same Paper showed that the boiling point and the chemical activity changed at the same time as the electrical resistance, which suggests the idea that there is some molecular change taking place at that temperature, probably one of dissociation of more complex into simpler molecules, and that this conveys the current across an otherwise insulating body, somewhat after the manner of electrolysis in solutions.

Action of Light on Sulphur.

That the metals of the same group in the arrangement according to the periodic law have properties in common is well known. Thus chlorine, bromine, and iodine belong to the same group, and are in many respects very similar bodies. Sulphur belongs not only to the same group as selenium, but is the next element in front of it. Naturally, therefore, we expect that they will have properties

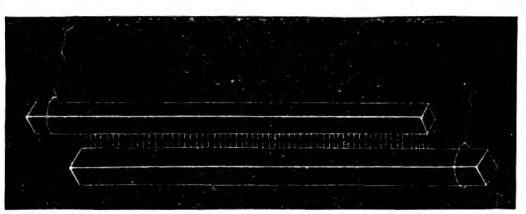

Fig. 3.

in common, and possibly the action of light in the case of the former may be shared in an inferior degree by the latter. This appears more probable from the well-known fact that a saturated solution of sulphur in bisulphide of carbon is rendered turbid by direct sunlight, part of the sulphur being changed and becoming insoluble in that liquid. A portion of the sulphur undergoes the same change when exposed to a high temperature. In order that the sulphur used in the experiment might be as sensitive as possible to light, it appeared desirable that only pure soluble sulphur should be used, and that great care should be taken not to raise the temperature in melting it so high as to produce any of the insoluble modification.

Two rectangular graphite rods (Fig. 3) were placed parallel to each other, the one projecting about an inch at one end, the other at the other end.

The edges were turned towards each other, as shown in the figure, leaving a space of one millimetre, which was filled with melted sulphur. This was levelled off with a hot iron to make the portion between the corners as thin as possible.

A quadrant electro-meter was charged, and the graphite rods, separated by sulphur, inserted between the binding screws, so that the negative quadrant was connected with the positive one through the sulphur (1·5 centimetre long, 1 millimetre thick, and 1 millimetre broad).

The electrometer was charged to the same potential in each experiment in a series and allowed to run down for a certain time. Sunlight was allowed to fall on the sulphur, but shaded from the rest of the apparatus; when not required the ordinary window-blind was drawn down.

Of course the electrometer and sulphur were protected from induction by surrounding bodies by wire screens.

The following three series of readings were taken on different days, and in one or two cases clouds interfered with the experiment, especially in No. 8, when the light was considerably shaded by cloud:—

—	Scale deflection at the beginning.	Time.	Fall in scale divisions.	State.
		minutes.		
1st series (1).....	180	30	20	Dark.
,, (2).....	,,	15	20	Light.
,, (3).....	,,	35	18	Dark.
2nd series (4)	300	15	25	Light.
,, (5)	,,	17	25	,,
,, (6)	,,	15	20	Dark.
,, (7)	,,	15	19	,,
,, (8)	,,	15	20	Light.
3rd series (9)	200	15	14	Light.
,, (10)	,,	15	17	,,
,, (11)	,,	16·5	16	,,
,, (12)	,,	15	10	Dark.
,, (13)	,,	15	10	,,

The first and second series were alternated dark and light in the same set of experiments to see that no permanent change was produced and mistaken for the effect sought. In the first the time varied and the deflections were allowed to fall the same distance; in all the others the time was the same and the fall varied.

The method of performing the experiments made it possible that the effect might be produced by the heat of the sun and not by the light. The variation in temperature observed on a delicate thermometer was about 1° C. To eliminate the effect of heat, a long series of observations was made in the dark, whilst the temperature was raised slightly by placing a Bunsen flame 4in. or 5in. away from the screen protecting the sulphur, and the heat radiated by placing an iron spiral in it, then one of copper, and lastly a fine-clay tile.

The range of temperature was 15·2° C. to 17·1° C. in the first ten experiments, in which the heated ones fell rather more slowly than those at a lower temperature. In the next seven observations the range was 14·8° C. to 18° C., the fall being exactly the same in each.

There yet remained the possibility that the light falling on the wires which held the rods caused the charge to escape more quickly into the air. When, however, the sulphur was removed, the effect produced by the light on the portions of wire exposed to its influence was too small to produce any change in the rate of fall.

Hence it appears that although selenium is the body most sensitive to the action of light, it shares its property with its neighbours, and the three elements (constituting the same group), sulphur, selenium, and tellurium, are all similarly acted upon, furnishing another example of the importance and beauty of the law which classified them together.

"THE ECONOMICS OF ELECTRIC LIGHT AND POWER STATIONS."

In connection with the interesting series of Papers by Mr. A. P. Wright under the above title, Part I. of which we have recently reprinted from our Boston (U.S.) contemporary *Modern Light and Heat*, several correspondents were not able fully to understand the load diagram, which is reproduced below from our issue of March 8th. We have, therefore, addressed a letter to the editor of our contemporary, requesting him to be good enough to ask the author for some further explanation. The following reply is printed in *Modern Light and Heat* of April 25th:—

"TO THE EDITOR OF 'MODERN LIGHT AND HEAT.'

"SIR: In reply to your favour enclosing communication from the editor of *The Electrician* of London, *in re* my recent articles in *Modern Light and Heat*, I have to request that, in addition to the explanation I give below, you will also convey to that gentleman my appreciation of the endorsement the articles referred to have received by their republication in *The Electrician*.

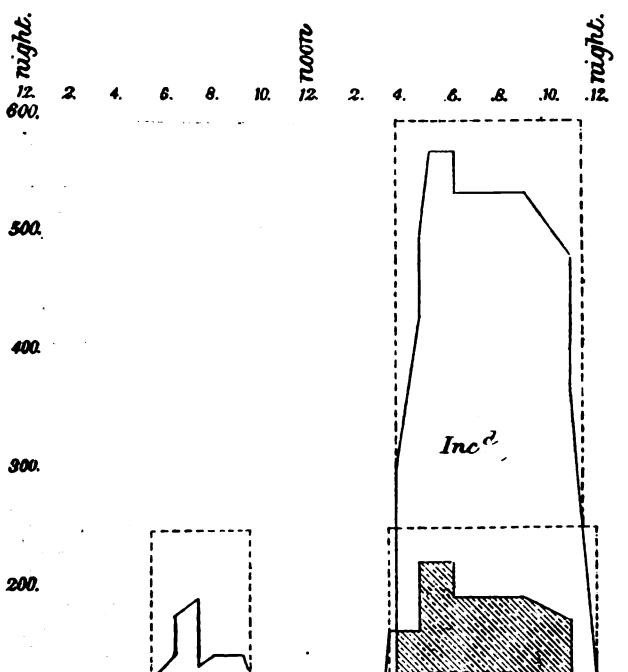
"In further explanation of the station output it may be stated that the curve represents the variations in indicated horse-power during the twenty-four hours of one of the shortest days in the year—Saturday—and in it are shown not only the total indicated energy used but the various amounts required for the different classes of electrical work. Referring again to the diagram, it will be observed, following the curves, that 'commencing at 12 o clock

Digitized by Google

at night, the power required is uniform' for some time, about 60 horse-power for 2,000 candle-power arc lamps used for street lighting and the balance of the energy being consumed for incandescent lamps. The incandescent output naturally increases as the world begins to wake, and is indicated by the curve. The composition of the load is shown at all times by the sectional areas of the curve, that marked '2,000 candle-power' representing not only the amount of energy consumed by the street lamps but the duration of this lighting. In the same way the areas sectioned in the opposite direction and marked *motor* indicate the period and amount of power transmitted to motors. The area marked '1,200 candle-power, likewise represents the time occupied in commercial arc lighting, while the unsectioned area marked 'Inc.,' which is the complement to the others, represents the details of incandescent lighting.

"It was not intended at this period in the articles to enter into the details of the composition of the load, as it was proposed to show several of these curves for different days, such as Saturday, Sunday, and ordinary days, both winter and summer, when taking up the question of recording readings of current and power, in a section of the articles which is to follow later on, and which will deal with 'Operation and Management.'

"The object of using the curve, which is one of a set to be used later, was to indicate the economical subdivision of the power units in such a way as to keep the engines working within their economical limits, as shown by the dotted lines in the diagram. Referring



The vertical scale is the power scale, in units of 100 horse-power.

to the diagram it will be noticed that at twelve o'clock at night the dotted line indicates the use of an engine of 125 horse-power until about 4:30 a.m., when one of a capacity of 250 horse-power takes its place until about nine o'clock, when the first engine is again called into use. As the day darkens and the lights turned on require more power a 250 horse-power engine is started and the 125 horse-power stopped, and a little later a larger engine of 350 horse-power is started and coupled with the 250 horse-power. If the power curve is compared with the areas enclosed by the dotted lines it will be evident that for a short period only can the engines be working disadvantageously. The curves which will be used to illustrate these articles are all prepared from data actually obtained during the operation of a station similar to that described.

"In reply to the question as to the difference in the average lamp hours, 2,095—as compared with the supposed average on the other side of from 700 to 800 hours—it may be stated that in this case there is no assumption of lamp-hours, the figures being actually deduced from the curves for twelve months, and the apparent excess can easily be accounted for if it is remembered that in the particular case dealt with the lighting is entirely business lighting, and that a considerable amount of light is used during the day, as indicated by the diagram; and the list of customers includes a great many who use their light until eleven and twelve o'clock and all night, while there are very few house lights to reduce the average, as would be the case if general lighting were done.

"The first article is intended to be the result of a discussion as to the advisability of entering into the lighting business, and with a view to arriving at a basis upon which an engineer is to prepare plans and estimates. The articles to follow will present plans and estimates; will deal with construction, both inside and outside; with distribution and with management and operation, the various duties of the manager, his staff, and a system of records and reports, by means of which a proper analysis of the cost of production may be arrived at.—Yours truly, "ALEX. P. WRIGHT."

SOME RESULTS WITH SECONDARY BATTERIES IN TRAIN LIGHTING.*

BY ALEXANDER S. BROWN.

It is now four years since the Pennsylvania Railroad, appreciating the advantages of electric lighting for this purpose, began a series of experiments with the secondary battery for the illumination of parlour cars. I am unable to give the cost of lighting by any of the batteries referred to, as the expense appears to have been a secondary consideration compared with the necessity of securing the best system of illumination. During the summer of 1884, experiments with the Brush storage batteries were commenced at the Altoona shops of the Pennsylvania Railroad, and continued through the fall and winter of that year. These experiments were made by Dr. Dudley, and proved so successful that eight parlour cars, which were being constructed at that time, were equipped for incandescent lighting and put into regular service on the 1st of April, 1885.

The Brush cells used consisted of three plates each, two negative and one positive, the amount of surface of the positive plate being equal to that of both the negatives. These plates differed from those now used, there being no paste in their composition. The negative is designed to give the greatest possible surface from the least weight of material. The positive plate measured 8″ × 9″ × 1″ and the negative 8″ × 9″ × ½″. These batteries are rated at 70 ampere hours, but the hard usage they received soon reduced their capacity, and at the end of a year's time the positive plates were almost entirely destroyed. In fact I have taken plates out of the cells which had holes in them fully four inches in diameter, while the deposit in the bottom of the cell would be from an inch to an inch and a-half in depth. The plates also had a decided tendency both to buckle and grow, and in a number of cases it was a very difficult matter to remove the plates without injury to the cell; you will understand, of course, that I allude more particularly to the positive plate. The weak points in the Brush battery were the small number of ampere hours per pound of material—about two I believe. There was a tendency to buckle and sulphate, and the arrangement for connecting the plates was such that there was oxidation at the junction, causing the plates to break when subject to the motion of the car. This last feature was a source of endless trouble to us, and as is usually the case, was sure to happen at a time or place where it was impossible to repair the break. While using the Brush battery the cars were wired with the battery boxes, one on each side of the car, coupled together in series, each box holding three trays, and each tray containing four cells, this giving a total of 24 cells to a car, or an E.M.F. of 48 volts.

The lamps used originally were of the Brush-Swan type, with small platinum loops projecting from the base, these hooking into a socket, and held in place by a spiral spring, this socket fitting into another one, to which the connections to the wires were made. After using this style for some time an improved pattern of Brush-Swan lamp was substituted, but the great drawback to this lamp was its frailty, the breakage per day often averaging 4 per cent. of the total number of lamps in use on all the cars. These lamps required about 45 volts and 1 ampere of current, and each car contained 10 lamps, seven in the body, one in the smoking room and one in each vestibule, thus using about 10 amperes of current, and as the batteries were rated at 70 ampere hours, we should have obtained from six and one-half to seven hours' good light, but it was very seldom, after the batteries had been used for a short time, that we could get over five and one-half hours. As will readily be seen, this could hardly be called economical, for to obtain five or six hours' light we were obliged to charge from 15 to 20 hours with a Brush arc light dynamo giving a current of about 10 amperes. Then taking the weight into consideration, each time the car needed charging, the trays, six in number, and weighing 1,200lb., had to be loaded on the track, pulled over to one side of the car, and the discharged trays taken out and the freshly charged ones put in their place. The remaining three were then taken around to the other side of the car and changed in the same manner. As the cars invariably stood on a double track it was necessary to carry half the trays for some distance, over tracks, &c. Then, again, the tracks were usually full of cars, and if there was not sufficient time for them to be parted, the batteries had either to be carried under the car or over the platform. Under the present system this has been done away with to a great extent, as will be explained subsequently. During the month of December, 1886, we commenced using one battery of the 7 B type, manufactured by the Electrical Accumulator Company. This battery was a decided improvement over those pre-

* A Paper read before the American Institute of Electrical Engineers, New York, May 22, 1889.

Digitized by Google

viously used, giving as it did nearly double the number of ampere hours for the same weight of material. After using this battery for about a year the positive plate began to give way, and new ones were substituted, the negatives, however, being retained, they not having deteriorated; in fact, we are still using the negative plates of our original 7 B battery. This battery proved to be so satisfactory that in June, 1887, we added two more of the same type and two manufactured by the Julien Electric Company. The latter batteries were similar in size and shape to the 7 B type of the Accumulator Company, but did not seem to stand the hard usage so well, as they would crack instead of buckling, and allow a large quantity of the paste to become loosened and fall out. It is proper to state, however, that these plates were made especially for us to fit the cells we were using, and were not of the regular Julien type. This, no doubt, will account in a great measure for their failure to keep up the standard of the present type of Julien batteries. After the positive plates of this battery became worthless, and not having any others to put in their place, we decided to make a kind of consolidated affair and see how Julien negative and accumulator positive plates would work together. The result was extremely satisfactory, and we have had no trouble with them whatever, excepting the occasional buckling of a positive plate.

During the fall of 1887, we began substituting the Accumulator batteries for the Brush batteries, and by the end of the year we were using them altogether, with the exception of the two Julien I have mentioned. We, however, kept 96 of our best Brush cells, to be used in case of an accident to the incandescent dynamos, which are used to supply the current for the railroad telegraph as well as for lighting the passenger station.

After the change in batteries had been made, it was thought best to change the system of wiring the cars, so that instead of its being necessary to put batteries on each side of the car, we need only put them on one side, and get the same amount of light. This was done by connecting the two boxes under the car in parallel, and substituting 23-volt Edison lamps for our 45-volt Brush-Swan lamps. After doing this we found that we were able to get as many hours light from 12 cells as we formerly did from 24. Of course this change reduced the expense of lighting the cars considerably, for where we formerly had a change of battery for each car, or 48 cells, we now needed only 24 cells per car, with a few extra ones to be used in case the 12 cells would not be able to supply sufficient light for a long trip. This system of lighting proved so successful that it was decided to substitute it for gas in the remaining seven parlour cars. The wiring of these cars was commenced at the Meadow shops, near Jersey City, last September, and has just been completed. These cars are arranged for the 23 C type of the Accumulator Company's battery, and 19 B type of the Julien battery. The battery boxes under the cars are larger than the old style and contain four trays, or 16 cells, the lamps we used taking 23 volts E.M.F. Changes were also made the first of the year in the system of charging, and the batteries are now charged from an incandescent dynamo instead of an arc, thus enabling the batteries to be charged with any amount of current desired. In connection with this description of the four years' work of the Pennsylvania Railroad, I would like to add something in regard to the electric lighting of the Chicago limited express.

In 1887, the Pullman Palace Car Company commenced using the electric light on one of three trains of the New York and Chicago limited express, and the charging of the batteries at Jersey City was given into the hands of the Pennsylvania Railroad Company. The batteries used were the 7 B type of the Electrical Accumulator Company, 30 cells to a car, and usually there are six cars in the train. These batteries would furnish enough light for one trip, and each time the train arrived at either terminus it was necessary to replace them with freshly-charged cells. This was not objectionable at Chicago, for the train arrived there in the morning, so that they could be charged during the day, but in Jersey City, where the train did not arrive until evening, the work was very difficult on account of the dynamo being in use for other purposes. After this one train had been running a short time, another one was fitted up, 19 B type of Julien battery being used. It was thought that this would give us a chance to see which was the better of the two batteries, but they both worked very well considering the treatment they received. After Mr. Bauer became connected with the Pullman Company, he did away with charging the batteries at the ends of the line, and introduced a Brotherhood engine and Eickemeyer dynamo in the baggage car of each train in order that the batteries might be charged in transit. When the train leaves Jersey City, the baggage car is on the rear, and consequently no charging is done until it leaves Philadelphia, where the train is reversed, bringing the baggage car next to the locomotive. The batteries are charged continuously until the train reaches Chicago, and the same practice is continued on the return trip. The steam for driving the Brotherhood engine is taken from the locomotive boiler, and the exhaust is used for heating the train.

So far as the Pennsylvania Railroad is concerned the electric lighting of passenger trains may be considered an assured success, and leading as it does to the abolition of kerosene lamps, and incidentally encouraging the adoption of steam heating, the safety and comfort of the passenger is certainly increased.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 29, 1889.

A most important piece of legislation has just been approved by the Governor of the State affecting particularly the street railways of this city. For a long time past some of the railroad companies have been seeking to obtain powers by which they might run their cars with other than animal power, but hitherto they have been unable to effect their purpose. During the last meeting of the New York Legislature a Bill was introduced and passed allowing the companies to employ other than animal power, and Governor Hill has now signed the Bill. This is an important measure, from the fact that some of the companies which it is likely to affect have a very large equipment of horses, and are among the largest street railway companies in the world. Thus, for example, the Seventh Avenue Road is operating 227 cars with 1,900 horses; the Central Park Company has 165 cars, with 1,200 horses; the Dry Dock Company has 185 cars and 1,017 horses; the Eighth Avenue has 112 cars and 1,155 horses; the New York and Harlem, or Fourth Avenue Company, belonging to theVanderbilts, has 162 cars and 1,250 horses; the Sixth Avenue Road has 117 cars and 1,100 horses; the Second Avenue Road has 316 cars and 1,780 horses; the Third Avenue Road has 391 cars and 1,800 horses, and the Twenty-third-street Road has 93 cars and 850 horses. I have enumerated these figures which by no means include all the roads in the city, for the purpose of showing how large is the street railway plant employed in New York, and what an immense number of horses is required to operate them. These horses, of course, are scattered all over the city in huge stables, occupying ground of almost fabulous value, and yet under such conditions as cannot be considered healthful either for the horses or for the people in the neighbourhood. Moreover, during the summer time, the trouble with the horses under the intense heat, becomes very serious, and on holidays and Sundays, just when roads should do their heaviest work, they are crippled because of the utter inadequacy in the inverse ratio of the animal power required to move the cars. The new Bill having been passed, we may look for some important developments. The Fourth Avenue Road will probably go in even more heavily than it has done for electricity, with the Julien storage batteries, but at first on other roads the probability is that the cable will be pretty extensively introduced. The Third Avenue Railroad Company have been operating a cable road on the outskirts of the city with a good deal of success. It has proved an immense convenience to the road and passengers, and hence nothing is more likely than that the Third Avenue Company will at once extend the cable service over its whole system, and operate by that means from Harlem Bridge to the City Hall, beneath the elevated tracks of Mr. Jay Gould's Manhattan Company. There is one point of difficulty which presents itself, however, and that is the fact that the city is just preparing to spend £600,000 on new paving, and it certainly will not do to have this paving put down only to be pulled up again a few months after by the cable contractors. Probably some sort of compromise or working arrangement will be arrived at, but in the meantime it is hoped by electricians that the occasion will before long give them an opportunity to do part of the work which now promises. It may be noted, in passing, that the Bentley-Knight people have not so far felt called upon to put their conduit system in operation down town on Fulton-street, although the tracks and conduits have been ready for some months past. Perhaps now that the new law has removed all doubt as to the legality of using electricity, the company owning the road will go ahead and put its whole plant in operation. From Boston the news comes that the West End Company has been disposing of large blocks of its land in the suburbs to raise money for the equipment of its vast electric system, using the overhead trolley and it is said that in a few days contracts will be given out for as many as a thousand electric cars. As you are aware the West End Company are already operating Sprague, Bentley-Knight and Thomson-Houston cars with success on the out-

Digitized by Google

lying portions of their system, but what they now have to do is to replace by electricity their present equipment of 775 box cars, 806 open or summer cars and 7,684 horses. Surely it will be a good day for the horses when they are thus released from the slavery of street-car service and their places taken by the hardy and never weary electric motor.

One of the cities which has recently been considering it good policy to put in an electric light plant of its own is Bangor, Maine, which last week had the pleasure of seeing a fine new Brush plant go into operation at the city waterworks. The pretty city of Bangor is supplied with water from the Penobscot River, the works being situated about one and a-half mile from the centre of the city. Until about a year ago water was forced into the mains by a 3,000,000 gallon pump operated by three powerful turbines, but it was found necessary to increase the service, and hence a new system of turbines and pumps was put in, leaving idle the old outfit. It then occurred to some of the city authorities that the disused water plant might be used to run an electric light plant owned by the city, which was then paying about $9,000 a year for its street illumination by arcs, gas jets, and naphtha lamps. The local Thomson-Houston Company then offered to do the whole lighting at the rate of about $8,400 a-year, but it was determined to leave them out in the cold and to put in this new plant, the cost of operating which is put at about $5,000 a-year. It is interesting to note that poles are used, the city having put up no fewer than about 800 cedar poles from 30ft. to 35ft. high, and over 40 miles of overhead wire. As the example of Bangor will probably be followed by other places in New England, it can be understood that this movement is watched with some little apprehension by local companies that have invested large sums of money in the plant under the reasonable assumption that such of the public lighting as was to be done by electricity will be given to them. It will be readily understood, too, that were the city thus goes into the business it very often does its citizens more harm than good. Where the plant has both the city and the commercial lighting there is a chance of doing a good business or operating at a profit; but when the public lighting is thus taken away, what remains is hardly worth looking at. This difficulty has already been experienced in one or two New England towns where the city authorities have attempted, but unsuccessfully, to secure the right to engage in a general and commercial electrical business. There are, of course, two objections to this. One is that the city thus drives out of business altogether some of its most enterprising citizens who have started their plant in the reasonable belief that they would have public support and not municipal competition, and the other is that for a city to undertake to give all the electrical service that is required of it would necessitate the raising and expenditure of a far larger sum of money than it is wise for any community to guarantee the interest on.

The propriety of inflicting sentence of death by electricity in this State was discussed this week in connection with the appeal on behalf of the murderer Kemmler. As I stated in my last, Mr. Bourke Cockran, one of the most prominent of the younger advocates at the New York Bar, undertook to fight the case for Kemmler, distinctly disavowing, however, any connection with the Westinghouse people, whose apparatus it has been proposed to employ, much against their will, for administering the fatal shock. Mr. Cockran appeared before the Court at Auburn on June 25th, and made a very forcible statement as to the legal merits of the case. He pointed out that the constitution of the State forbids the infliction of cruel or unusual punishment, and he held that no State Legislature had the right to inflict a punishment which was not within the contemplation and meaning of the constitution, whether national or State. He found an interesting precedent in the case of Feltom, who killed the Duke of Buckingham, and who asked that his hand might be cut off as a punishment, when it was held by the judges that the right to inflict torture had no place in English jurisprudence. Mr. Cockran insisted that the only knowledge which the Commission had obtained as to the effect of the electrical current was gained by experiments with dogs and other four-footed beasts, while no facts had been elicited which would go to show that the condemned man may not suffer the most exquisite torture. He wished to know whether the Court would tolerate the burning of a criminal at the stake in the city market-place, and whether it would allow a man to be hanged and then cut down and disembowelled before life was extinct. Yet while the Court would certainly not allow such practices as that, it would be as much at fault if it allowed the uncertain electrical method to be applied. The State should not experiment with human life. Mr. Cockran closed by offering to prove his allegation that the punishment was unusual and cruel, and could not be lawfully inflicted, and although he was followed by the Attorney-General of the State, who argued that the law was constitutional, and that the Legislature had the power to inflict death by electricity, the Court decided that evidence was necessary to enable it to decide the question; and the case was further adjourned until July 30, evidence to be taken in the meantime before a referee. Thus you will see, as I ventured to predict, there is not a little delay in carrying out capital punishment by the new means, and in many quarters the opinion begins to prevail that at the next meeting of the Legislature the law will be repealed, and that ordinary rope will be declared good enough.

From time to time one hears interesting stories as to the ageing and general improvement of wines and liquors by electricity. You will doubtless remember the experiments made not long ago by Mr. Edison, who placed an incandescent lamp in a barrel of whisky, with the result of greatly improving the quality of the spirit. I believe that this experiment was carried out on various occasions, but I do not think that the process has been regularly developed anywhere in a practical way. News now comes from California, however, of some work that has been done in San Francisco by a Mr. F. M. Speed, who, it appears, is ageing Californian wines by winding wire around the cask in which the wine is contained, and passing heavy currents through the coils. The time of treatment is 18 to 25 days, after which period, it is said, the wine has lost its harshness and shows many of the qualities of wine that is properly aged. It is also said to be unusually agreeable to persons of weak digestions, while it has the charming characteristic that it no longer causes headache. There is no doubt that should Mr. Speed carry out his amiable intentions and avert by means of his wire-wound barrels the consequences that are apt to follow the midnight revel, he will be regarded as a benefactor by a large portion of the human race. Henceforth, then, the enthusiastic toper can look upon the wine when it is red with impunity, provided it has been "electroplated," as the Californian papers phrase it.

Some very interesting work is being planned by the Committee on State and Municipal Legislation, which was appointed at its recent Chicago meeting by the National Electric Light Association. With forty odd legislatures almost incessantly at work it can be readily understood that the various electrical companies are likely to be greatly harassed and vexed by laws passed ostensibly to promote the public welfare. In more than one State the electric light interest has been attacked and seriously imperilled, not only by measures introduced into the legislature but by ordinances introduced in the municipal councils, and it is felt that the time has arrived when co-operative action in the way of watching such measures and fighting them is imperatively needed and can do great good. Hence it is that the Committee in question has been appointed by the National Electric Light Association, and is already getting ready for grappling with the problems of legislation that arise from time to time. The chairman of this Committee is Mr. A. R. Foote, whose recent book on the "Economic Value of Light and Power" is probably familiar to some of your readers. Just at this time, as I showed at the beginning of my letter, considerable interest is taken in the question of the purchase of electric lights by the municipalities, and it is seen that in a great many places where companies have already been established under State and Municipal sanction it will amount to little short of robbery if, by the establishment of city plants with the proceeds of taxation, to which they have themselves contributed, they are deprived of the business which they were the first to develop, and which they have built up by hard work.

PHOTOGRAPHING LIGHTNING WITH A MOVING CAMERA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been experimenting with a Wimshurst machine giving sparks one inch and a-quarter long. I have photographed several of these sparks and enclose copies of two. The one which is of a ribbon-like form was taken while the camera was being shaken up and down with the hands, and the other was taken with a fixed camera; and if there is time to move a camera during the time an inch and a-quarter spark is visible, and produce a ribbon-like form of flash, it proves that ribbon lightning would be the result of moving the camera during the time a flash of lightning was visible. To me it seems almost impossible for any one to hold a camera in his hands to photograph the lightning without jerking it when the discharge takes place.—Yours truly, A. W. CRAMP, jun.

225, Bethnal Green-road, London.
July 9th, 1889.

[The photographs enclosed show in one case a very sharply defined flash, and in the other a thick ribbon-like discharge.—ED *E.*]

THE ELECTRIC LIGHTING OF MARIENBAD.

A correspondent writes as follows:—"The above central station, which has been erected for the town and authorities of Marienbad by Messrs. Ganz and Co., was opened on the 30th of last month. It was originally intended to supply 35 arcs for public use and about 1,200 glow lamps for private customers. The applications for the latter were, however, so much in excess of what was expected that the plant was much enlarged. The present output is 1,800 glow and 48 arc lamps, in addition to those used for public lighting, as above mentioned. The station is at a distance of over a mile from Marienbad, and covers about 700 square yards. There are four sets of machines, one being always in reserve. Each set consists of a 50,000-watt Zipernowski alternator, driven direct by an 80 horse-power Westinghouse engine at 500 revolutions, and a 3,000-watt exciter driven from the same source by a belt. Each set stands on its own separate foundation. The leads, both primary and secondary, are carried on poles about 30 metres apart. The transformers have cast-iron bases and sheet-iron covers; those for public lighting are on poles, those for private use are some on poles and some in the houses. After midnight the public arc-lamps are turned out and glow-lamps substituted.

LEGAL INTELLIGENCE.

United Telephone Company v. Liversedge and Co.

The action of the United Telephone Company *v.* Liversedge and Co. was heard on Saturday last, before Mr. Justice North, in the Chancery Division of the High Court of Justice.

Mr. WICKLEM said the action came on upon motion for judgment in default of defence. The action was brought for an injunction to restrain the infringement of the Edison transmitter and the Bell receiver, and the claim asked that the infringing instruments might be delivered up to the plaintiffs. With the statement of claim particulars of breaches were delivered, and he asked for an order in the same terms in which the Courts had previously made them, with costs up to judgment, the costs of the inquiry as to damages being reserved.

His LORDSHIP made the order as asked.

A similar order was made by Mr. JUSTICE CHITTY in an action of the United Telephone Company *v.* Brierley, which was heard as a short cause, the defendant not appearing.

COMPANIES' MEETINGS & REPORTS.

Crompton and Co. (Limited).

The Right Hon. Viscount Torrington presided yesterday at the City Terminus Hotel, Cannon-street, over the first annual general meeting of the members of Crompton and Co. (Limited).

The SECRETARY (Mr. Francis R. Reeves) read the notice convening the meeting.

The following is an abstract from the report of the directors:—The net profits admit of the payment of dividends both on the Preferred and Ordinary Shares. After payment of the interim dividend in January last, and providing for vendors' interest and other payments shown in the accounts, there remains a surplus of £5,433. 2s. 7d., which the directors propose to dispose of as follows:—(1) To carry to a suspense account a sum of £1,500 as a provision for doubtful debts and contingencies. (2) To place a sum of £568 to a reserve fund for equalising future dividends. (3) To declare a dividend of 7 per cent. per annum on the Preference Shares. (4) To pay the managing directors their fees of £1,000, according to the Articles of Association. (5) To declare a dividend of 5 per cent. per annum on the Ordinary Shares.

The sum of £4,594. 11s. 6d. has been expended upon enlargement of the works at Chelmsford, and for additions to plant and fixtures. The works are thus rendered much more efficient for economical manufacture, and when the new offices which are in course of construction are completed much time and expense will be saved in the management of the business.

Digitized by Google

Contracts for lighting have been agreed with the Corporations of Folkestone and Chelmsford, and orders for central stations for several provincial towns are practically arranged for. The business of the company with the Australian Colonies is rapidly increasing, so much so that the company's agents, Messrs. Harrison and Whiffen, have requested that additional capital may be provided by means of a separate company, to which they would themselves largely subscribe. An Australian company has accordingly been registered, and a circular on the subject will shortly be forwarded to the members of this company. The Directors' report was taken as read.

The CHAIRMAN: I have now to move—

"That the report of the Directors, and the audited statement of accounts for the year ended March 31 last, be and are hereby approved and adopted."

Gent'emen, the Directors feel that they may congratulate the shareholders upon the satisfactory position of the Company, as shown by the statement of accounts which has been laid before you. The Company has been barely a year in existence, and only eight months of this time are comprised in the report, yet the net profits are above the average of those of preceding years. It will be seen from a perusal of the accounts that the directors have, while maintaining the buildings and plant in complete repair, written off a sum of £1,554 as depreciation. They further propose to carry forward £1,500 to provide for any possible contingency that may arise and for doubtful debts, though there can hardly be expected to be many of the latter, as the accounts are not a year old. They then propose to place a sum of £568 to reserve fund for the purpose of equalising future dividends. It may be said that this is not a large sum; still, it is a beginning, and considering that the Company has only been working eight months, it may be looked upon as a very fair start. In making these deductions from the profits before declaring a dividend, the Directors feel that they are acting prudently as men of business, and that they are doing their best to make the position of the Company a strong one. It is only fair to add that the holders of the Ordinary Shares cheerfully acquiesced in these proposals, though in doing so they are depriving themselves of so much more profit. I mean, of course, Messrs. Crompton and Albright. After setting aside these sums the Board proposed to pay the full dividend of 7 per cent. on the Preferred Shares to the 31st March; then to pay the Managing Directors their fees, which they are not entitled to draw until the dividend is paid on the Preferred Shares, although the Company has the full benefit of their constant attention; and finally it is proposed to pay a dividend of 5 per cent. on the Ordinary Shares. So much with respect to the past. The future looks very promising. The works are busy, and orders are constantly arriving. There is just now a great revival of the electrical industry, consequent on the passing of the Electric Lighting Act Amendment Bill. Many new companies have been formed, and the Board of Trade, after holding an inquiry into the applications for Provisional Orders and Licences which have been made under the Acts, has officially sanctioned many of the projects. Manufacturers are consequently very busy, this Company, in common with many others, having a large increase of orders. The Directors believe that a very prosperous future is before them, and every effort is being made, by careful attention to details, to ensure that the work shall be executed in such a manner as to keep the name of the Company in the front rank of reliable makers. A circular and prospectus of the Australian Company referred to in the report have been sent to the members, and these papers fully explain both the object of the new company and the reason for its formation. The Directors believe that this Australian Company has every likelihood of being a prosperous one. Messrs. Harrisson and Whiffen have done good work in Australia, and the business is rapidly growing. The Directors have every confidence in recommending subscription to the shares of that Company. I may mention that the Australian Company which has been formed, and of which I have agreed to be Chairman, is merely another form of having a house in Australia, where our business will be transacted perhaps better than if we merely had a firm out there to look after it. The Australian Company are bound to take all their material, &c., from Crompton and Company. At the date of the report only 16,781 shares had been allotted, but up to this date the shares placed number 18,816. There are thus less than 1,200 shares left, and no doubt they will be placed very shortly. I think it is a question whether we ought not to put a premium on the balance that we have still left. However, that is a matter the Directors will take into consideration. I understand that there is a question which has appeared to be rather of a knotty kind to some of the shareholders—the question, that is, of the patents and goodwill, the sum against that item being £37,765. That represents the value of the business over and above the actual realisable assets handed over to the Company by the vendors. If any gentleman would like to have any further explanation I would ask the secretary, who is well versed in the figures, to give the information. I now move the resolution.

Mr. R. E. B. CROMPTON: Gentlemen—In rising to second Lord Torrington's motion, I have great pleasure in addressing you for the first time since the formation of the Company, as I was unfortunately absent at the first meeting. Being the vendor, this might, of course, be a somewhat serious moment for me to meet you, the business having been turned into a limited liability company. I am, however, glad to say that I feel very comfortable in thus meeting you. The business I was very proud of as a private firm, and I am, and I believe I shall continue to be, equally proud of it as a limited liability company. There has been among some people a sort of prejudice against the Limited Liability Companies' Acts. They say that firms that have done extremely well as private firms do not continue to do so well when turned into limited liability companies. That statement has been frequently made, and I think in some cases it is only too true; but some of the finest businesses in this country are working on the lines we are working this Company on—that is, that the original owners who built up the business shall remain the principal shareholders, as is the case here. When I look at such firms as Messrs. Marshalls, of Gainsborough, the finest set of engineering works in the world, I only hope that we shall be able to follow in their footsteps, do equally good work, and gain such a world-wide reputation. I may say that the objects we had in view in obtaining additional capital by the formation of this Company have been already partially attained. We have been able to take up many large contracts which we could not have dreamt of when we were hampered for want of capital. As a result our order-sheet is better filled up than it was at any time since we commenced. I can corroborate every word your Chairman has said as to the hope of future prosperity. A firm situated as we are, with very considerable works and very considerable engineering power, have a revenue from two sources—keeping the works fully employed, and in the second place, turning the brains we may have to useful account. I refer more particularly to my co-director and myself and our superior engineers. It was not until the passing of the Electric Lighting Act that we were able to get any scope at all for that latter part of our assets, for it is an asset. All my training and all Mr. Albright's training has come from actual experience and spending our own money in the past; and such experience is now bearing fruit, for we are getting a line of orders which means very small risk to the Company's capital, and it brings in profits. We are ourselves doing our best to increase the number of electric light and supply companies, and we are in negotiation with several towns in addition to those named in the report, but for reasons which you will all appreciate we do not mention those towns here. They are not absolutely completed, and our rivals are very apt to step in and snatch the cup away from us before we get it to our lips.

Mr. R. TUFNELL inquired what percentage of depreciation had been charged for plant, buildings, &c. The £1,554 in the profit and loss account for depreciation appeared at first sight rather small on so large a sum as £44,133 standing in the balance-sheet as the value of the stock-in-trade, plant, tools, &c.

The SECRETARY stated that 2½ per cent. had been written off the buildings account, and 7½ per cent. off the plant and machinery. The auditors thought that 2½ per cent., considering that they kept the buildings of the company in repair, should not be continued in the future, and he (the speaker) agreed with them; but it had been thought advisable to make the depreciation in question on this occasion. As to the subject of patents and goodwill, referred to by the Chairman, there were many meetings and negotiations before the Company was formed, at which he (the speaker) was present, and that item stood at a very much larger figure in the original negotiations—as much as £70,000. It was originally intended that the preferred capital should be £70,000, and the ordinary capital £70,000, but the result of their negotiations satisfied those who were coming into the business that £70,000 would not be sufficient to provide for the purchase of the business and to furnish sufficient working capital. After negotiations, that sum was increased to £100,000, but the figure of £140,000 was retained, the vendors giving way to the extent of £30,000 of ordinary shares. The £40,000, taken as a round figure, was supposed to represent the actual value of the business other than realisable assets. The vendors desired to get an increased capital for extending the business, and they offered the large preferential dividend of 7 per cent. Having done that they thought they would be justified in retain a large holding as Ordinary Shareholders, and that amount was agreed, after considerable discussion, at £40,000. As, however, the actual realisable assets exceeded £50,000 by about £3,000, the £40,000 resolved itself into the figure in the balance sheet of £37,300.

A SHAREHOLDER: That represents the Ordinary Shares?

The SECRETARY: Yes.

Mr. ALBRIGHT stated that while in the office that morning a gentleman, who was one of the engineers of one of the most important South American Railways, came into the office and referred to certain orders that had recently been placed with them. He incidentally told the speaker that a plant, which their Company had supplied to his Company over two years ago—a considerable order—had already considerably more than paid for itself in the saving it had effected for them, owing to the fact that by using the electric light they could unload wagons and, generally speaking, carry on their business by night as well as day. The gentleman in question also stated that the Company's plant was so satisfactory to them that, although in sending out their tenders they had received tenders lower than those of the Company, they had unhesitatingly given their orders to those from whom they had received satisfaction in the past. The Company kept on receiving orders, but he did not think it was necessary to go into them. He thought that the particular incident he had mentioned might interest the shareholders.

The CHAIRMAN put the motion and it was carried unanimously. He afterwards stated that since the formation of the Company they had elected as Directors Mr. Bernard Gibson and Mr. Carleton Fowell Tufnell, two gentlemen who were likely to bring great strength to the Company, and he was sure they would materially advance its prosperity. They had been duly elected by the Board, but he would like to have their election confirmed by the shareholders.

On the motion of the Rev. O'BRIEN HODGE, seconded by Mr. J. HILL, a resolution was accordingly passed confirming the election of the gentlemen named.

Mr. R. TUFNELL afterwards moved, and Mr. HODGE seconded, the re-election of Messrs. Duncan, Bryce, and Co. as auditors, and the motion was agreed to.

A SHAREHOLDER inquired when the dividend would be paid.

The SECRETARY: This evening.

Mr. TUFNELL then proposed a vote of thanks to the Chairman and Directors for their able management of the Company's concerns.

Mr. HY. COX seconded the motion, which was carried unanimously.

The CHAIRMAN, in returning thanks, assured the shareholders that the Directors would do their best to promote the welfare of the Company.

Digitized by Google

Their interests were identical with those of the shareholders. He could not let that opportunity pass without recognising the services of Mr. Reeves (the secretary), who was his (the Chairman's) other right-hand man.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

A half-yearly general meeting of the Company was held at the Cannon-street Hotel, on Thursday, "for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income tax." Mr. S. William Silver presided.

The SECRETARY (Mr. Wm. J. Tyler) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I think I may say that we have pleasure in meeting you here to-day, and perhaps unusual pleasure. We have to report to you that the general trade has been quite equal, somewhat in excess, of that of any previous year. Our electrical and telegraph departments have been fairly occupied. Two of the steamers have been employed. One returned only last Saturday after laying little short of 1,000 miles of cable on very difficult ground. This expedition was under the direction of our engineer-in-chief, Mr. Hamilton Gray. It was successful in every respect, notwithstanding the peculiar character of the coast, ground seas, the delta of the Congo river, and the varying nature of the bottom—all showing us and the public generally that a practical knowledge of the manufacture of a cable is not only desirable but essential to carry out an undertaking, as this has been, in the most successful way, at once uniting practical knowledge with scientific skill. I take it upon myself to say that I think the Silvertown Works will not be found wanting in this respect. The preparations for the expedition, from the experience of our engineer, whose name I have given you, were such as afforded us every satisfaction in reference to the sanitary condition of those on board, and the whole work has been carried out in the most satisfactory way—well within the time—and efficiently in working. I therefore think you will say that we are thoroughly justified – or that I am as the representative of my friends here—in moving that a 5 per cent. dividend, or 10s. a share, free of income-tax, should be payable on the 12th inst.

Mr. MATTHEW GRAY: I second that.

The CHAIRMAN inquired if any shareholder had any question to ask, or any remark to make, and no one rising to address the meeting, he put the motion in the usual manner, and declared it carried unanimously, adding that that concluded the business.

Mr. J. L. HANSON said that before separating the shareholders had a duty to perform to the Directors, particularly after the satisfactory statement of the Chairman. He begged to move a vote of thanks to the Chairman and the Directors for the care and attention they had bestowed on the management of the Company's affairs, and also for the great success which appeared to result from their endeavours.

Captain VEREY said he had very much pleasure in seconding the resolution, but he thought they ought to include in the vote the name of Mr. Gray, who had so successfully looked after the expedition referred to by the Chairman.

The motion was carried unanimously.

The CHAIRMAN: I can only thank you in the name of my friends sitting on the right and left of me, and I will undertake to communicate Captain Verey's special rider to my young friend, Mr. Hamilton Gray, who richly deserves it. I should also like to include those who were with him, a careful body of men and the captain. I may say that the vessel returned to her moorings on Saturday last within an hour of the time appointed, the work having been carried out in the most successful way.

The meeting then separated.

The Eastern Telegraph Company (Limited).

Report and accounts of the Directors for the half-year ended 31st March, 1889, to be presented to the thirty-fourth half-yearly ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on Thursday, the 18th inst., at one o'clock:—

The revenue for the period amounted to £435,932. 3s. 10d., from which are deducted £92,448. 14s. 6d. for the ordinary expenses and £48,665. 14s. for expenditure relating to repairs, renewals, and laying of cables, &c., during the half-year. After providing £3,710. 5s. for income tax, there remains a balance of £291,107. 10s. 4d., to which is added £36,616. 1s. brought from the preceding half-year, making a total available balance of £327,723. 11s. 4d.

From this amount there has been paid—

Interest on Debentures and Debenture Stock	£28,274	13	2
Dividend on Preference Shares	20,474	2	8
An interim dividend of 1¼ per cent. on the Ordinary Shares	50,000	0	0
	£98,748	15	10

leaving a balance of £228,974. 15s. 6d., from which £118,000 has been carried to general reserve.

The Directors now recommend the declaration of a final dividend for the year ended 31st March, 1889, of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, both payable on the 18th inst., free of income-tax, and making, with the three previous payments on account, a total distribution of 13s. per share, or 6½ per cent. for the year, on the Ordinary Shares. The balance of £974. 15s. 6d. shown at the foot of the revenue account is proposed to be carried forward to the next half-year.

The revenue includes £81,441. 12s. dividend and bonus for the half-year upon the Company's investments in the Eastern and South African, the Black Sea, and the Direct Spanish Telegraph Companies.

Since the last general meeting, the Eastern and South African Telegraph Company has completed the extension of its cables along the West Coast of Africa, connecting Cape Town, Port Nolloth, Mossamedes and Benguella with Loanda, where the cables of the West African Telegraph Company terminate, thus establishing an alternative line of telegraphic communication between Europe and the Cape of Good Hope, and completing the telegraphic circuit of the African continent. The Directors believe that the accomplishment of this important work will be highly satisfactory to the shareholders of this Company, which is largely interested in the Eastern and South African Company, and to the public.

An agreement has been entered into between this Company and the other telegraph companies interested in the South African telegraph business, by which the telegrams to and from South Africa will be transmitted either by the East Coast or West Coast route on joint account, and the receipts divided between them in equitable proportions.

A convention has been entered into between the French Government and this Company for laying a cable between the Company's station on the island of Perim and the French settlement of Obock.

The several sections of this Company's cables are in good working order.

NEW COMPANIES REGISTERED.

THE CHILI TELEPHONE COMPANY (LIMITED).—Registered by Slaughter and May, 18, Austinfriars, E.C., with a capital of £250,000 in £5 shares. Object, to carry into effect an agreement made between W. A. Pittman and the Chili Telephone Company (Limited), and to purchase, acquire, construct, equip, maintain and work any lines of telegraph, telephones or other means of communication in Chili and the adjoining countries, and generally to carry on the business of a telegraph, telephone and electric light company. There shall not be less than three nor more than seven directors.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.

PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.
SOLE PROPRIETORS of the British, Indian and Colonial Patents,
THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

The first to be appointed by the subscribers to the Memorandum of Association. Qualification £1,000 stock. Remuneration to be determined in general meeting.

CROYDON ELECTRIC SUPPLY COMPANY (LIMITED).—Registered by Saxelby and Faulkner, 7 and 8, Ironmonger-lane, E.C., with a capital of £5,000 in £5 shares. Object, to construct within the borough of Croydon works for distributing the electric light. Registered without Articles of Association.

DEVON AND CORNWALL ELECTRICITY SUPPLY COMPANY (LIMITED). Registered by Slaughter and May, 18, Austinfriars, E.C., with a capital of £100,000 in £5 shares. Object, to form centres in Devon and Cornwall at which electric power may be generated or accumulated for the purposes of street, house lighting, &c. One of the first subscribers is Mr. R. Hammond, 117, Bishopsgate-street, E.C. There shall not be less than three nor more than seven directors. Qualification, £250 stock. Remuneration: £500 per annum divisible, and one-tenth of net profits after 7 per cent. dividend.

DUTTON AND CO. (LIMITED).—This company was registered on the 29th ult., with a capital of £60,000, in £10 shares, to acquire the business and goodwill of Dutton and Co., mechanical engineers, electricians, and signal manufacturers. The number of directors is not to be less than two nor more five; remuneration, £50, to be divided as they may determine.

ECUADOR TELEPHONE COMPANY.—This company was registered on the 4th inst., with a capital of £100,000 in £5 shares, to acquire or construct telegraphs, telephones, and other means of communication in Ecuador and the adjoining countries. The signatories and arrangements for management are the same as those of the Peru Telephone Company, a notice of which appears above.

THE HENLEY TELEGRAPH AND ELECTRIC CONSTRUCTION COMPANY (LIMITED).—Registered by Newman, Hays and Co., 31, Abchurch-lane, E.C., with a capital of £200,000 in £10 shares. Object, to carry on, as principals or agents, the business of electricians, telegraph engineers and contractors, submarine and telegraph instrument manufacturers, &c., and for the purpose to acquire lands, works, property, and premises wherever convenient, and the machinery and patent rights belonging to W. T. Henley's Telegraph Works Company (Limited), and the goodwill, property, and other rights connected therewith; to carry on the business of an electric light company in all its branches, and in particular to erect any works requisite for the business of the company wherever expedient and convenient. The first subscribers are:—F. Newton, 16, King William-street, E.C.; W. Hays, 31, Abchurch-lane, E.C.; H. Lescher, 6, Clement's-lane, E.C.; Lieut.-General Sir J. Stokes, K.C.B., Good Rest, Hayward's Heath; S. Gedge, M.D., 1, Old Palace-yard, Westminster; G. Baird, C.E., Travellers' Club, Pall-mall; The Hon. H. S. Littleton, 22, Rutland-gate, S.W. There shall not be less than three nor more than nine directors. The first to be appointed by the subscribers to the Memorandum of Association. Qualification, 50 shares. Remuneration, £2,000, and further £150 for every 1 per cent. of dividend over 10 per cent.

THE KINGSTON-UPON-HULL ELECTRIC LIGHTING AND SUPPLY COMPANY (LIMITED).—Registered by F. B. Moss, the Outer Temple, Strand, W.C., with a capital of £1,000, in £1 shares. Object, to establish at Kingston-upon-Hull an electric light company. Registered without Articles of Association.

LEICESTER ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—Registered by Walter Webb and Co., 23, Queen Victoria-street, E.C., with a capital of £1,000 in £10 shares. Object: To produce and supply electricity or electrical currents, and to undertake public or private lighting. Registered without articles of association.

SCHOTH'S ELECTRO-MEDICAL APPARATUS COMPANY (LIMITED).—Registered by Danell and Co., Finsbury-chambers, E.C., with a capital of £10,000 in £1 shares. Object: To carry on all the businesses hitherto carried on by G. A. Schoth, of Euston-road, for manufacturing electro-medical and scientific instruments, and also the manufacture of medical and surgical instruments. Registered without Articles of Association.

THE PERU TELEPHONE COMPANY (LIMITED).—Registered by Slaughter and May, 18, Austinfriars, E.C., with a capital of £100,000 in £5 shares. Object, to carry into effect an agreement made between W. A. Pittman and the Peru Telephone Company (Limited) to acquire any lines of telegraphs and telephones in Peru. There shall be not less than three nor more than seven directors. Qualification, £1,000 stock; remuneration to be determined in general meeting.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended July 5, 1889, amounted to £4,068.

CUBA SUBMARINE TELEGRAPH COMPANY.—For the month of June the receipts of this Company show an increase of £273 as compared with the corresponding period.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY.—The directors of this company have, subject to audit, decided to recommend at the meeting of shareholders to be held on the 30th inst. a dividend of 7 per cent. for the year ending 30th June, 1889, on the A shares, and a further distribution of 3 per cent. against arrears of cumulative preferential dividend on those shares.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company for the month of June, 1889, amounted to £22,600. From the 1st January to 30th June, 1889, they were £129,400, against, in the corresponding months of 1888 and 1887, £132,000 and £127,120 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 5, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,791.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—At the Board meeting, held on Wednesday last, the directors declared an interim dividend of 5s. per share, free of income-tax, in respect of the first half of 1889, payable on the 18th inst.

NATIONAL TELEPHONE COMPANY (LIMITED).—It is stated that . F.Mr R. Leyland has been elected president, and Colonel R. Raynsford Jackson and Mr. James Staats Forbes have been elected vice-presidents of this company. The registered offices of the company have been removed from 162A, Queen Victoria-street, to Oxford-court, Cannon-street, London, E.C.

PERSONAL.—We are informed by Mr. A. H. Vesey, A.M.I.C.E., that he has taken offices at 12, Draycott-place, Sloane-square, S.W. Mr. Vesey, we are glad to learn, has several important installations on hand at present, amongst which are Prince's Club and Brooks' Club.

——— The firm of Siebe, Gorman and Co., of Westminster Bridge-road, submarine and electrical engineers, has been dissolved. Mr. W. A. Gorman will carry on the business in future by himself.

DISSOLUTIONS OF PARTNERSHIP.—The dissolution of the partnership between Messrs. A. Thompson and Robert T. Turnbull, electrical engineers, of Connaught-mansions, Victoria-street, London, S.W., was announced in Tuesday's *Gazette*.—The Hon. C. A. Parsons has retired from the firm of Messrs. Clarke, Chapman, Parsons and Co., of Gateshead-on-Tyne, by mutual consent, and under the style of Messrs. C. A. Parsons and Co., of Park-lane, Gateshead-on-Tyne, will carry on the electrical branch of the business of the original firm, who will in future be known as Messrs. Clarke, Chapman and Co.

REMOVAL.—Messrs. Spagnoletti and Crookes inform us that they have removed their offices and factory from Adelaide Works, Uxbridge-road, to larger premises at Goldhawk Works, 39B, Goldhawk-road, W.

CRICKET.—The following matches, which have been recently played by the Carcavellos Club (Eastern Telegraph Company's Station), will be of interest to some of our readers:—May 30, Carcavellos *v.* Victoria—Carcavellos, 108 and 93; Victoria, 63 and 93. June 13, Carcavellos *v.* Lisbon—Carcavellos, 208; Lisbon, 45 and 78. June 20, Carcavellos *v.* Victoria—Carcavellos, 194 and 13 (for one wicket); Victoria, 65 and 141. June 28, Carcavellos *v.* Lisbon—Carcavellos, 86 and 122 (for four wickets); Lisbon, 132 and 72.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

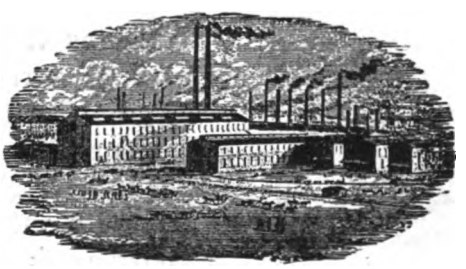
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Johnson & Phillips.
Nalder Brothers & Co.
Paterson & Cooper.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

MANVILLE & MADGEN, *Managing Directors.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 583.—Vol. XXIII. FRIDAY, JULY 19, 1889. Price Fourpence.

NOTES.

The Report issued by the Board of Trade at the beginning of the month respecting its proceedings under the Electric Lighting Acts forms a concise summary of the steps taken during the past twelve months by the Board of Trade with regard to the applications of the various electric lighting companies, the chief facts of which are already well known to our readers. After giving a list of the applicants for Provisional Orders, and referring to the "Model Order" and the correspondence thereon with the London County Council, the Report proceeds as follows:—"Some of the alterations, however, which proposed to extend the jurisdiction of the County Council, or to transfer to it duties entrusted by Parliament to the Vestries or District Boards as the local authority, the Board of Trade were unable to concur in. They considered that such substantive changes in the existing law should not be effected by a Provisional Order, but, if necessary, should be carried out by an Act of Parliament of general application, after full discussion." We are extremely glad to find that the Board of Trade is after all of our opinion on this point, although it is rather difficult to reconcile its statements with its actions.

The wholesale transfer to the London County Council of "duties entrusted by Parliament to the Vestries" which formed such a marked feature of the "Model Order" forms if anything a still more marked feature of the batch of Provisional Orders now before Parliament, the name of the County Council occurring at least a dozen times in these Orders where it did not occur in the Model Order. The alterations in the Orders granted by the Board of Trade, although not of the first importance, tend so far as they go to place the Undertakers in a less advantageous position than they held under the Model Order. For instance, the County Council may now, with the approval of the Board of Trade, prescribe the hours during which the Undertakers are to carry out work in connection with distributing boxes. Again, any person demanding an electric supply has now only to contract for a minimum of two years instead of three years. On the other hand, the County Council, which was empowered by the Model Order to summarily remove and sell, after the manner of the New York Board of Control, all overhead wires which were still in position at the end of two years, is now obliged to attain the desired result by the less exasperating process of fine. It is, we think, to be regretted that more alterations of this character have not been made in the Orders now before the Select Committee.

With regard to some of the numerous electric lighting projects in the provinces announced in our last week's issue, we confess to a feeling of uneasiness. Many of the companies are, no doubt, perfectly sound and honest concerns, but others were never heard of till yesterday, and their intended *modus operandi* remains an unknown quantity. The question of *personnel* is one of no small importance—from our point of view the name and record of the engineer and electrician of a Construction Company, to say nothing of the promoters, are second only to the question of the soundness of its finance. And even with Supply Companies who do not necessarily design or erect their own central stations the difficulty of finding a thoroughly capable technical staff will sometimes be seriously felt. In most cases we suppose that the task of laying (as well as maintaining) the underground mains will devolve upon the local electricians, so that men with any real experience in this direction should find themselves shortly at a premium. Our chief anxiety is that the best men should fill the best posts, and that directors should realise more thoroughly than at present they seem to do the vital importance of the appointments which they have to fill. As regards some of the promoters, it is hard to say whether the public is most to be admired for its short memory or its long suffering. We can only stand by and silently wonder.

We have remarked in our leading column on the admirable way in which the accounts of the London Electric Supply Corporation were rendered at its general meeting last Monday. Both in form and in matter they are a pattern of what such accounts ought to be. The Act of 1882 requires that electric supply companies shall furnish their accounts on a model approved of by the Board of Trade. This model ought, we think, to be of uniform application. The balance-sheet and accounts referred to, we are informed, have been issued with the Board's approval; and we should say that it could not do better than adopt it as a model for the guidance of all the other supply companies.

Having safely established its monopoly of manufacture, the Edison-Swan Company has celebrated the event by issuing a new and revised price list. Naturally the trade would expect that after beating all its opponents in the Law Courts and obtaining the costs of its litigation the victorious company would signalise its triumph by reducing its charges; and so it has. Prices are reduced, *but so are the discounts.*

We should be sorry to see the Technical Education Bill, which has now reached the Committee stage, either rejected or delayed through any cause whatever; but the display of animosity on Monday evening when an amendment extending the scope of the Bill to Voluntary Schools was hotly opposed might well justify its withdrawal if anything could. Lord Hartington took fright at the suggestion, regretfully predicting that the Bill, if saddled with that provision, would not be allowed to pass either this session or the next. And apparently he was right, for there immediately followed not merely predictions but threats that the Government should rue it if the attempt to place Voluntary Schools on a footing with Board Schools proved successful. On the other hand, the friends of Voluntary Schools were equally determined the Bill shall not pass unless the equality they demand is conceded.

Between the two contending parties the Bill may probably be sacrificed; and almost certainly will exclude Voluntary Schools from its operation if carried. A deplorable example of partisan and sectarian animosity is revealed in this otherwise ridiculous squabble. Both sections are anxious to provide technical instruction; but one of them is even still more anxious that the other shall get none of the State help which is to be liberally given to itself. In other words, technical education is good for the rising generation, but not for those who attend other than Board Schools. This attitude might be pardonable if Voluntary Schools were entirely self-supporting, for then they could expect no external assistance for technical any more than for ordinary schooling. But in reality considerable grants in aid are annually voted by the State to Voluntary and Board Schools alike, where the educational standard required by the State is maintained. This being the case, it is logically impossible to withhold from Voluntary Schools the assistance for technical instruction accorded to Board Schools under the present Bill. The claims of Voluntary Schools appear still stronger when we remember that they cost the nation extremely little although they do a large proportion of the educational work of the country.

In an article on Electric Radiation in the current number of the *Phil. Mag.*, Dr. Lodge observes that an electrostatic charge upon the surface of the sun would if disturbed oscillate to and fro with a period of 6·6 seconds. He therefore suggests that "It may be worth while to suspend at Kew a compass-needle with a natural period of swing of 6·6 seconds, and see whether it responds to solar impulses." These waves would be twelve hundred thousand miles in length. A charge upon the surface of the whole earth would have a period of only one-seventeenth of a second, so that it would be somewhat difficult though not perhaps impossible to detect its presence in this way. Prof. J. J. Thomson has calculated that the period of oscillation of an electrostatic charge upon a conducting sphere is equal to 1·4 times the time taken by light to traverse the diameter of the sphere.

Our New York correspondent this week gives a brief description of a very simple method which has been devised by Mr. Nikola Tesla to start a synchronising motor and bring it to synchronism without external aid. Ingenious as the system is, we do not think it will meet with much favour in this country, since it involves the use of an earth return during the period of starting.

Hamburg.—This town has just voted £11,000 for lighting the two Jungfernstiege of the Alsterdamm.

The Scotch Universities Commission.—Sir Wm. Thomson has been appointed a member of the Scotch Universities Commission.

Chesterfield.—Messrs. Crompton and Co. have applied for powers to supply electricity in the Borough of Chesterfield for public and private purposes.

Rochdale.—Three electric lighting companies have announced their intention to the Town Council of applying for powers to supply electricity within the borough.

Rugby.—A notice has been received from the Midland House-to-House Electricity Company of their intention to apply to the Board of Trade for a Provisional Order.

Darwen.—The Municipal Electric Power Corporation have caused a notice to be served upon the Town Council of their intention to apply for a Provisional Order.

Cape Town.—The Cape Town Council has refused to grant to a local firm a concession for ten years of the exclusive right of supplying the electric light in Cape Town.

Poplar.—The Metropolitan Electric Supply Company have intimated their intention to apply for powers to supply electricity within the district of Poplar Board of Works.

Airdrie and Coatbridge.—The Lighting Committee have been instructed to consider and report upon the proposals of the Scottish House-to-House Electricity Company.

York.—Six electric lighting companies have given notice to the Town Council that they propose to apply for Provisional Orders authorising them to supply York with electricity.

Kidderminster.—The Western House-to-House Electricity Company have intimated their intention to apply for a Provisional Order for the supply of electricity within the borough of Kidderminster.

Incandescent Lamps and Lamp Holders.—The Edison-Swan Company have just issued a new illustrated circular list of prices and particulars of their well-known incandescent lamps, lamp holders, &c.

Crediton.—At the last meeting of the Crediton Improvement Commissioners a letter was read from the Devon and Cornwall Electric Lighting Company announcing their intention to apply for Parliamentary powers.

Barry.—The lighting of the new docks at Barry Island has been carried out by Messrs. Crompton and Co., who have installed 41 3,000 candle-power arc lamps, and 600 16 candle-power incandescent lamps.

Winter Sessions.—The 1889-90 Session of University College, Bristol, opens on the 9th October. Full particulars respecting the Electrical Engineering course will be found in our advertisement column.

Leith.—Five electric lighting companies have given notice to the Leith Town Council that they intend to apply for Provisional Orders. The matter has been remitted to the General Committee for consideration.

London Chamber of Commerce.—The following, amongst many others, were elected members of the London Chamber of Commerce at the last Council Meeting:—The Westinghouse Electric Company; James Taylor (Telegraph Manufacturing Company, Limited), Telegraph Engineer; and Richd. S. Waring (Waring Cable Company), Electric Wire and Cable Manufacturer.

Smethwick.—Notice has been served on the Smethwick Local Board by the Midland House-to-House Electricity Company that

Digitized by Google

they intend applying to the Board of Trade for powers to supply electricity in Smethwick.

Fleetwood.—The Fleetwood Improvement Commissioners have resolved to hold a special meeting to authorise an application to the Board of Trade for powers to supply electricity for public or private purposes in the district.

Middlesborough.—A communication from the Yorkshire House-to-House Electricity Company has been received by the General Purposes Committee, in which the Company gives notice of its intention to apply for a Provisional Order.

Hamilton.—The Scottish House-to-House Electricity Company having intimated that they intend applying for a Provisional Order to introduce electric lighting into the town, it has been resolved that the Town Council should themselves apply for an Order.

Keighley.—Two electric lighting companies have given notice to the Town Council of their intention to apply for Provisional Orders. The Town Clerk has been instructed to inform them that their proposals will be strongly opposed by the Corporation.

Newcastle.—At a meeting of the Newcastle Town Improvement Committee on Wednesday last week notices were given of applications on behalf of two electric light companies. The two companies referred to are independent of the two companies already established.

Simla.—Various improvements, says *Indian Engineering*, are being introduced in the Viceregal Lodge at Simla. The lodge is being connected by telephone with the Foreign Office, and a wire will probably be carried on to the Home Office, which is distant about two miles.

Canterbury.—Notices have been received by the Town Council announcing the intention of the Electric Construction and Maintenance Company, and of the South of England House-to-House Electricity Company, to apply for powers to supply electricity within the district.

Burslem.—The Town Council has received notices from the Midland House-to-House Electricity Company and the Municipal Electric Light and Power Corporation of their intention to apply for Provisional Orders authorising the supply of electricity within the borough.

Glossop.—A notice has been received by the Town Council from a London electric lighting company stating their intention of applying to the Board of Trade for powers to light the Borough of Glossop with electricity. A resolution was passed inviting the company to carry out their project.

Halifax.—Communications were read at the last meeting of the Town Council from the Electric Construction and Maintenance Company and the Yorkshire House-to-House Electricity Company, announcing their intention to apply for Provisional Orders to supply electricity within the borough.

Crumpsall.—At the last meeting of the Crumpsall Local Board the Clerk stated that he had received a communication from the Manchester House-to-House Electric Company giving notice of their intention to apply for a Provisional Order, and asking the consent of the Board to the application.

Haslingdon.—At the last meeting of the Haslingdon Local Board the Clerk read a communication from an electric lighting company with registered offices in Bond-street, giving notice that they intended to make application for a Provisional Order. The matter was referred to the Lighting Committee.

Ipswich.—At a meeting of the Ipswich Paving and Lighting Committee last week, the Clerk read a communication from the Midland House-to-House Electric Company, giving notice that they intended to apply for a Provisional Order, and asking the formal consent of the Corporation to such application.

Barnsley.—At the meeting of the Town Council on Wednesday the Town Clerk reported that he had received notices from the National Electric Company, the Yorkshire House-to-House Electricity Company, and the Municipal Electric Light and Power Corporation, of intention to apply for Provisional Orders.

The City of London.—The Anglo-American Brush Electric Light Corporation, the Metropolitan Electric Supply Company, and the Laing, Wharton, and Down Construction Syndicate have given notice of their intention to apply to the Board of Trade for Provisional Orders to supply electricity within the City of London.

Kirkcaldy.—At a meeting of the Kirkcaldy Town Council on Monday last week, the clerk reported that he had received notice of the intention of the Scottish House-to-House Electricity Supply Company to apply for a Provisional Order. After some discussion the matter was remitted to a committee to inquire into. The Committee subsequently advised the Council to oppose the application, and this was agreed to.

Hanwell.—At the last meeting of the Hanwell Local Board notices were received from the South-Western District and Thames Valley Electric Supply Company and from the Electric Supply Corporation to the effect that they intended to apply for Provisional Orders for the purpose of introducing electric lighting into the Board's district.

Okehampton.—The Okehampton Town Council has referred to a committee a communication from the Devon and Cornwall Electricity Supply Company, asking for the consent of the Council to an application of the company to the Board of Trade for a Provisional Order to authorise the supply of electricity for public and private purposes within the borough.

Electric Traction on the Underground Railway.—In the report of the Metropolitan Railway Company, issued this week, it is announced that the agreement with the Electric Traction Company has been cancelled, and an offer is now under consideration from another quarter to make a trial without cost to the railway of a direct system of electric traction.

Liskeard.—At the last meeting of the Town Council a communication was received from the Devon and Cornwall Electricity Supply Company, soliciting the consent of the Council to an application to the Board of Trade for a Provisional Order authorising the company to supply electricity for public and private purposes in the urban district of Liskeard. It was decided to defer giving consent.

Limehouse Board of Works.—At the last meeting of this Board, notice was received from the Solicitors to the Metropolitan Electric Supply Company that application is intended to be made for a Provisional Order for the Limehouse District. A similar notice was received from the Solicitors of the London Electric Supply Corporation. The communications were referred to the Works Committee.

Brussels.—The electric lighting tenders have now been opened. Six offers were received. The firms tendering were l'Electrique, of Brussels, the Compagnie Internationale d'Electricité, of Liège; the Züricher Telephongesellschaft; M. van Rysselbergh, the Thomson-Houston Company, and Messrs. Siemens and Halske, of Berlin. The tenders have been taken into consideration, and will be reported upon by the Municipal College.

Withington.—At the last meeting of the Withington Local Board the Highways Committee reported that letters had been received from the Anglo-American Brush Electric Light Corporation and the Manchester House-to-House Electricity Company announcing their intention to apply for Provisional Orders to enable them to supply the district of Withington with the electric light. The clerk was instructed to ask for further information.

Cardiff.—A special meeting of the Cardiff County Council has been summoned for the 12th August next to consider the notices of the five electric lighting companies who have announced their intention to apply for Provisional Orders. The Companies are Messrs. Crompton and Co., the Western House-to-House Electricity Company, the Anglo-American Brush Electric Light Corporation, the Electric Construction and Maintenance Company, and the Electric Trust.

Walsall.—The South Staffordshire Electric Lighting Company, the Midland House-to-House Electricity Company, and the Wolverhampton Electric Light and Power Company, have given intimation of their intention to apply to the Board of Trade for Provisional Orders authorising them to supply electricity for private and public purposes in Walsall. A Sub-Com-

Digitized by Google

mittee has been appointed to consider the question of the desirability of an application by the Corporation for a Provisional Order.

Chatham.—At a meeting of the Chatham Board of Health on Friday last, notices were read from the Municipal Electric Light and Power Corporation, the South of England House-to-House Electricity Company and the Electric Construction and Maintenance Company, stating their intention to apply for powers to supply electricity for public and private purposes within the district of Chatham. It was decided to acknowledge the letters and ask each company to forward a copy of their Order.

Blackburn.—Four electric lighting companies have given notice to the Corporation of their intention to apply for powers to supply electric light in the borough. The companies applying are the Municipal Electric Light and Power Corporation, the Electric Construction and Maintenance Company, the National Electric Supply Company, and the Lancashire and Cheshire House-to-House Electricity Company. The Corporation are about to consider the advisability of themselves applying for the necessary power.

The Winner of the Queen's Prize at Wimbledon.—Sergt. Reid, 1st Lanark Engineers, the winner of the Queen's Prize this year with the remarkable aggregate score of 281, is a telegraph clerk in the Glasgow Post Office. The only other telegraphist, so far as we can learn, who won a respectable position in the contest, was Sergt. Tee, Post Office Volunteers, an Instructor in the London Telegraph School, who scored 83 in the first stage, only one point short of the score which would have carried him into the second stage.

Paper Electrical Torpedoes.—Experiments have recently been made at Kiel by the German naval authorities on torpedoes made of paper and worked by electricity. The results are said to have been very satisfactory. The torpedo is about 11ft. long by 16in. diameter, and is made of twelve layers of paper 3½ millimetres (·14in.) thick, compressed and varnished. The motor is mounted on three paper ribs, and driven from the ship or shore by a cable, the steering and ignition of the charge being controlled through the same cable.

Hull.—At the last meeting of the Corporation Works Committee, the Town Clerk reported that he had been served with notices on behalf of five companies, stating that it is their intention to make application for Provisional Orders to authorise them to supply electricity for public or private purposes within the borough. The companies are as follows:—The Yorkshire House-to-House Electricity Company, the Kingston-upon-Hull Electric and Supply Company, the National Electric Supply Company, the Electric Construction and Maintenance Company and Crompton and Company.

The Belgrano (Buenos Ayres) Gas Company Bill.—The second reading of this Bill, which gave the Company power to supply electric light as well as gas in Buenos Ayres, was moved in the House of Lords on Friday evening last. The Earl of Morley said if this Bill were passed he thought it probable that other Bills receiving less support from shareholders would be introduced. The Lord Chancellor pointed out that if the Bill passed it would be difficult in future for the Chairman of Committees to clearly define his duty with regard to similar measures. The Bill was finally negatived.

The Influence of Humidity on Bifilar Suspensions.—While recently engaged in some magnetic investigations, M. Marchand, of the Lyons Observatory, noticed that the relative humidity of the room had a very marked influence on the indications of the magnetometer. In fact, when the dampness increases the bifilar suspension lengthens, the tension diminishes, and there is an apparent increase in the horizontal component of the earth's magnetism. M. Marchand is of opinion that this effect probably accounts for the connection which has been observed between the variations of the magnetic elements and meteorological changes.

Severe Thunderstorms.—Several thunderstorms of great severity have occurred during the past week in the Midlands and in the North. At Taddington (Beds.) a haymaker was killed by lightning. On Saturday a heavy thunderstorm broke over Luton and district, and a farm-house was set on fire. On the same evening a severe thunderstorm passed over Northampton, doing great damage, and at a village two miles outside the town a man was killed. On Monday, Annan was visited by a thunderstorm which lasted several hours. The village school of Dornock, near Annan, was struck by lightning and 18ft. of the roof torn off.

Burton-on-Trent.—At the last meeting of the Town Council the Gas Committee reported that they had received notice from three different companies of their intention to ask for powers to introduce the electric light into the town. The Committee considered that it was advisable for them to take some action with a view to retaining such powers in their own hands. They had therefore instructed inquiries to be made at large centres where the electric light was used. The three companies applying are the South Staffordshire Electric Lighting Company, Crompton and Co., and the Midland House-to-House Electricity Company.

Ayr.—Notices having been sent to the Ayr Town Council by the Scottish House-to-House Electricity Supply Company and by Messrs. Norman and Son, intimating that they intended to apply for Provisional Orders, the Lighting Committee reported that it was undesirable to allow any company or person not under the control of the local authority to obtain the extensive powers which the Board of Trade's license would confer, and they recommended the Commissioners themselves to apply to the Board of Trade for authority to supply electricity for public and private purposes within the Burgh of Ayr. This report was approved at the last meeting of the Town Council.

The Incandescent Lamp Agreement.—We have received a circular from the Anglo-American Brush Corporation, in which they notify that, under the arrangement they have come to with the Edison Swan United Electric Light Company, they discontinue the manufacture of Victoria incandescent lamps in the United Kingdom, and that with regard to the Victoria incandescent lamps now in use, the arrangement is that their customers shall not be disturbed or prevented from using such lamps, unless the Edison-Swan Company wish to replace them by lamps of their own manufacture, in which case they shall carry out the substitution without charge to the customers of the Corporation.

Paris Meeting of the Institution of Electrical Engineers.—The following circular has been issued to the members of the Institution, and the meeting will doubtless be well attended:—

"Dear Sir,—I beg to inform you that a joint meeting of the Institution and the Société Internationale des Electriciens will be held at Paris on Friday, the 23rd August, to be followed on subsequent days by excursions to places of scientific interest. As it is necessary in completing the arrangements that the Council should know how many members will probably attend, I have to request that if you purpose doing so, you will intimate such intentions on or before the 20th inst. A programme of the meeting will be issued, as early as circumstances will permit, to those members who advise me that they purpose attending it.—I am, dear Sir, yours faithfully, F. H. Webb, Secretary."

The Proposed Exhibition at Edinburgh.—At the last meeting of the Edinburgh Town Council the recommendations of the Lord Provost's Committee, that the Council should decline the request of the secretary of the proposed Exhibition to grant the use of the East Meadows as a site for the Exhibition, and that a sum of £1,000 should be voted to the guarantee fund provided the magistrates and council were satisfied as to the site and other arrangements, were agreed to. At the meeting of the Executive Committee of the Exhibition on Monday it was announced that the question of site would be settled in a day or two, and that subscriptions would shortly be invited. Sir Thomas Clark, Bart., has accepted the office of Chairman of the Executive Committee, and Mr. Lee Bapty has been appointed General Manager.

An Electric Scrutineer.—An apparatus has been devised by M. Le Goaziou, and has been favourably reported on in the French Chamber, to indicate the total of "ayes," "noes," and voluntary abstentions from voting whenever a division takes place in the Chamber. On every desk in front of a

Digitized by Google

member is placed a small box fitted with two handles, which the member works when registering his vote. The right handle registers his "aye," the left his "no," and both moved simultaneously indicate his abstention from voting. The results are printed by means of electro-magnets in a receiver, and are visible at a glance. Provision is made for a member to recall and correct his vote during the time allowed for the purpose.

Annual Excursion of the Liverpool Electric Supply Company's Staff.—The annual excursion of the staff and workmen of the Liverpool Electric Supply Company (Limited) took place on Saturday last. A number of Messrs. Callender's men also joined the party, which left Liverpool for Llandudno at an early hour. The dinner was held at the Westminster Hotel. Toasts were proposed to the Managing Directors, Messrs. Holmes and Vaudrey, and the Works Manager, Mr. A. Clough. The chairman (Mr. B. H. Collins) in a short address referred to the satisfactory growth of the company's business, and trusted it would still further increase now that a firm footing had been established in Liverpool as regards electric lighting. Boat-racing and other amusements were next indulged in, and the party then returned to Liverpool.

Fatal Accident at Brighton. — An inquiry was held at Brighton on Monday evening into the death of a man who had lost his life by coming into contact with an electric light wire. The deceased, Thomas Garman, was night watchman at Messrs. Hallett and Abbey's Brewery, and it was part of his duty to go to the roof to examine the liquor vat. Suspended at a height of between four and five feet over the stand from which this inspection was made was an electric light wire, and on Monday morning Garman was found lying there dead, with a mark half way round his neck as if grazed by the wire. A medical examination proved the man to have been perfectly healthy, and it was the opinion of Dr. Lowe that Garman had been killed by the electric current, his neck by some means coming in contact with the wire. The jury returned a verdict accordingly, and expressed an opinion that the wire, which had no communication with the brewery, had been very unsafely hung.

The London County Council.—At the meeting of the London County Council last week, the Highways Committee reported that notices of applications to be made next year for Provisional Orders had been received from the following companies:—Chelsea Electricity Supply Company, for Kensington, and St. George's, Hanover-square; Electricity Supply Corporation, for St. Giles's, Strand, Paddington, and St. Martin's-in-the-Fields; House-to-House Electric Light Supply Company, for Wandsworth, Fulham, and Lambeth; the Laing, Wharton, and Down Construction Syndicate, for the City of London; London Electric Supply Corporation, for the area of which the Council is the local authority; Metropolitan Electric Supply Company, for certain streets and places to be hereafter specified; Messrs. Renshaw, King and Co., for St. Margaret and St. John, Westminster; The Westminster Electric Supply Corporation, for St. Margaret and St. John, Westminster, St. George's, Hanover-square, St. Marylebone, and Paddington; a company (about to be formed) for Hampstead, Paddington, St. Luke's, Shoreditch, Clerkenwell, St. Marylebone, Kensington, Islington, Bethnal Green, Fulham, Hammersmith, Whitechapel, and Hackney.

Electrical Communication with Light-Vessels.—As long ago as the 22nd of February, 1887, a Committee was appointed by the Board of Trade to inquire into and report on the desirability of electrical communication between light-vessels and the shore, with the special object of facilitating the saving of life at sea; whether the system should be extended to lighthouses, and in other ways: and whether the experience gained by the present cable to the "Sunk" light-vessel has proved of sufficient value to justify the cost. The Committee (of which the Earl of Crawford was chairman), have presented their second and final report, which is now published as a Parliamentary paper. Herein they state that though the experiments carried on for the last four or five years show the possibility of establishing electrical communication, they remain of the same opinion as when they made their former report—that the expenditure involved in maintaining electrical communication between the "Sunk" lightship and the shore is not commensurate with the advantages gained, and they therefore recommend its discontinuance, and that the system should not be extended to lighthouses. They add that it would, as a general rule, be unadvisable to permit lightships which may be electrically connected with the shore to be used also as signal stations for commercial purposes. Sir Edward Birkbeck, M.P., who was on the Committee, dissents in one respect. He is strongly of opinion that a much more extended trial of the present electrical communication with the "Sunk" lightship should be carried out, and that for a further period of not less than five years.

Electric Lighting at Munich.—Dr. Voit, of Munich, has made a report to the Union Polytechnique showing the continued and increasing progress of the electric light. Nine electrical companies, three of which are especially interested in the municipal undertaking, have put down, for the lighting of Munich and its environs, 116 installations, comprising 588 arc lamps and 23,231 incandescent lamps, of which 4,900 are taken by the three Royal Theatres. Taking, from data furnished by the manufacturers, the mean candle-power of the arc lamps as 900, and that of the incandescent lamps as 16, the total quantity of candle-power supplied by the arc lamps is 529,200, and by the incandescent lamps 371,696, or adding the two together, a total quantity of 900,896 candle-power. There are 256 arc lamps and 6,687 incandescent lamps worked from gas-engines; 233 arc lamps and 14,610 incandescent lamps worked from steam-engines; and 90 arc lamps and 1,934 incandescent lamps worked by hydraulic power. The following table shows the candle-power obtained with each type of motor:—

Type of motor.	Candle-power from arcs.	Candle-power from incandescents.	Total candle-power.
Gas-engines	230,400	106,992	337,392
Steam-engines	209,700	233,760	443,460
Hydraulic motors.....	89,100	30,944	120,044

From statistics given by M. Diehl, it appears that in 1885 Munich had 30 electric-lighting establishments supplying 133 arc lamps and about 3,770 incandescent lamps. Reckoning as before the candle-power of each arc lamp as 900 and that of each incandescent lamp as 16, the light supplied by the arc lamps amounted to 99,700 candles, and by the incandescent lamps to 60,320, making a total of 160,020 candles. It will thus be seen that from 1885 to 1888 the quantity of light obtained from electricity rose from 160,020 to 900,896 candles.

Electrical Utilisation of Galvanisers' Waste Acid.—A correspondent of the *Engineer* says:—"In addition to the scheme mentioned last week for the utilisation of waste acids from galvanising works, which is the invention of Mr. Thomas Turner, Demonstrator in Chemistry at Mason College, another method of treatment has been discovered, and is now being perfected, by the chief chemist of Messrs. Elwell-Parker, Electrical Engineers, Wolverhampton. This latter scheme contemplates the treating of the waste acids mainly by electricity, and experiments have been proceeding for some time past with, it is understood, eminently encouraging results, which have been protected by patent. It seems likely that both inventors will have full opportunity afforded them of putting their discoveries to thorough trial, since Mr. Turner's method is likely to be taken up by some of the leading Birmingham sheet-iron galvanising firms, while that of the Electrical Engineering Company is intended to be taken up in a practical manner by certain of the Wolverhampton galvanisers. The system of adoption pursued in each case will probably be the granting of rights to several galvanising firms to carry out the process at their own works under royalty. What the merchantable products of the new processes are is at present a secret; but they are understood to be chemicals for which there is a large demand. Galvanisers, however, are glad to be promised relief from their troublesome 'pickle,'" We need scarcely say that this is by no means the first attempt which has been made to obtain some commercial return from the acid sulphate of iron which is produced in such enormous quantities in the process of cleaning or pickling iron sheets, either for tinning or "galvanising." The object aimed at is usually to recover both the iron and the acid, and there is of course no difficulty in doing this—the only difficulty is to make it pay. We shall be glad to be assured that the problem has at length received a successful solution.

LIGHTNING CONDUCTORS.—IX.

BY DR. OLIVER LODGE.

(*Continued from page 165.*)

Alternative Path Experiments in September, 1888—(*Continued*).

September 26, 1888.—I now arranged a new set of wires round the room, making them all the same length, and each enclosing a rectangle 475 × 875 square centimetres. The wires were of iron, copper, and lead respectively, a thick and thin wire of each. The length of each wire was 2,686 centimetres. The following are the particulars:—

Description of Wire.	Thickness.	Common Resistance.	Self-Induction.
	Millims.	Ohms.	Centimetres.
No. 12 Iron.....	2·40	·73	44,820
No. 27 „	·40	22·6	54,540
No. 12 Copper	2·35	·31	44,820
No. 27 „	·40	4·1	54,540
No. 11 Lead	2·90	·93	44,820
No. 23 „	·70	13·7	52,000

These wires were to be used as alternative paths, and the rest of the circuit was to be varied as seemed good. The object of this series of experiments was to examine more closely into the question of iron *versus* copper, to see whether the apparently anomalous result of iron wire affording a better alternative path than thick copper could be definitely repeated, and to determine the conditions under which the result occurred. At Bath I had promised to go into this matter more carefully, and at this time I had not worked out at all fully the theory of the alternative path experiments, so that I was in the dark as to the conditions under which the apparently anomalous result was to be expected.

The gallon jars already specified were employed. The A knobs were those of the universal discharger already described, and the machine was joined up to them with the intervention of pieces of wood pretty much as in Fig. 9, p. 164. The B knobs belonged to the spark micrometer.

The A spark length was 2·44 centimetres; its light not screened off the B knobs. The B knobs were adjusted till about half the sparks passed and half failed. The alternative paths were joined up to the B knobs by pieces of wire, each 122 centimetres long; at first of No. 12 copper.

Details of Circuit.	Length of B Spark with different Alternative Paths.			
	No. 12 Copper.	No. 12 Iron.	No. 27 Copper.	No. 27 Iron.
A knobs connected direct to jars	1·60	1·65	1·64	1·67
A knobs connected to jars by means of a couple of lengths of No. 17 copper wire, each 230 centimetres long and 0·15 centimetres thick, opened out to form a rough circle.....	1·88 1·83	1·87 1·83	1·77	1·745
Same, but with a couple of No. 27 iron wires used to join up the alternative paths to the B knobs (each wire 122 centimetres long) instead of the No. 12 copper pieces	1·76	1·74	1·76	1·79
Same, but with relative position of jars and connecting wires in the A part of the circuit interchanged.....	1·575	1·575	1·61	1·62
Long wires between jars and A knobs removed.....	1·535	1·535	1·57	1·62

Thus, then, under these circumstances, iron showed often some slight disadvantage as compared with copper, only in one case showing an advantage, and that not great. But it was noticed that the noise of the A spark was always distinctly enfeebled when the thin iron wire was in circuit.

The object of interposing different conductors between the B knobs and the main length of alternative path was to see if the first portion of this path had an exaggerated influence on the result. Hence the use first of No. 12 copper leads and then of No. 27 iron. No such exaggerated influence of the first portion was detected, however, nor is it now pointed to by theory.

I see no clear reason why introducing longish wires into the A part of the circuit should in one case lengthen the B spark and in the other case shorten it. The only obvious difference between the two cases is that in one case the wires were charged, forming part of the inner coats of the jar, while in the other case they formed part of the outer coats and were uncharged. The *de*crease they cause is natural (extra self-induction), but the only obvious reason for the *in*crease is their static capacity, which one would not suppose sufficient to make so much difference.

September 27.—Next day the gallon jars, standing ordinarily on a table, were connected direct to the knobs of the machine, these knobs being used as A spark (as in Fig. 5, Article I.), and the outer coats of the jars were connected to the alternative paths round the room by a yard or two of No. 18 copper wire. Length of A spark being about 3·52 centimetres, the following are the B spark readings when balanced against different alternative paths:—

Alt. Path.	B Spark.
No. 12 copper	The greatest length of B spark attainable was 4·15; it then nearly always failed. At 3·1 it nearly always passed. Sometimes it could be screwed up to the maximum without failing, and then, once it failed, it had to be screwed down to 3·6 or so before itcould go again.
No. 12 iron	3·1 or thereabouts. It fails mostly even at 2·9.
Thick copper again.	Went up to 3·4 or so.
No. 27 iron	At 2·65 it was half and half. At 2·8 it generally failed.
Thick copper again.	Generally passed at 2·85, nearly always at 2·8.
Thin iron again ...	Always failed at 2·8.

To compare these two leads more particularly, a couple of switches or bridges were employed, one of which switched in the thick copper lead, the other the thin iron; and it was clearly perceived many times that the B spark was both longer and stronger with the thick copper alternative path than with the thin iron. With the thin iron path it failed more frequently at a set distance between the B knobs, and when it occurred it sounded weaker, "showing distinctly that iron *does* cause a shorter and weaker spark than copper; but why? It must be the surgings in the conductor one is observing, and they are weaker in the iron." This is a quotation from my notebook at the time, and shows that the true explanation, subsequently confirmed by theory, was first suggested by experiment.

Experiments in Answer to Criticism.

September 28.—At Bath, Prof. Forbes questioned my mode of connecting up the alternative path to the outside of the jars, and though the objection does not bear critical examination, it was worth trying what difference there would be if the long wire were charged instead of remaining at zero potential. Accordingly the connections of Fig. 4, in the first of this series of Papers, was adopted. The A spark being set at 1·89, the following were the B spark lengths when balanced against the stated alternative paths, and just failing:—

No. 12 Copper round room	1·60
No. 27 Iron „ „	1·63
No. 27 Copper „ „	1·61

Practically all the same, but a trifle longest with the iron. To be sure that the wire was acting conductively, and not merely by static capacity, it was cut in the middle of its length, *i.e.*, at the far end of the room, and a six-inch length of silk thread interposed. The B spark length was now 3·5, everything else remaining the same. At the break in the wire long sparks could be got to discharging tongs, &c., and there was a slight noise or click at the cut gap at every failure of a B spark, a noise noticed by an observer standing near the gap before the sound of the A spark was audible across the room.

Experiments on Effect of Surrounding Medium.

At Bath, Mr. Preece suggested that the nature of the medium surrounding the wire would probably have an important influence in these alternative path experiments; and although I saw no reason for the supposition it seemed quite possible, so

Digitized by Google

to test it the following experiments were made at beginning of October, 1888 :—

A couple of pieces of wood, 17½in. by 16in. by ⅞in. thick, were edged with thin wooden flanges or projections, so that when wound with wire the wire would have a half-inch clear space between it and the wood. A length of 302in. of No. 12 copper wire was then wound on each frame in 8 coils, each coil having 2in. between it and the next, the pair of frames being wound exactly alike.

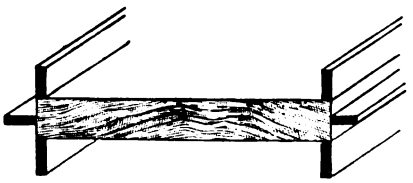

FIG. 10.—End of Wooden Frame for Coil.

Their equality was then tested by using them as alternative paths. The following are the B spark lengths (length of A spark, 1·51 centimetres) :—

——	No. 1 coil.	No. 2 coil.	No. alternative path.
Length of B spark, using pint jars	·928 ·928	·928 ·928	1·346
Using gallon jars	1·040 1·034	1·045 1·043	1.505

They are practically exactly equal.

No. 2 was now immersed in melted paraffin, in such a way that when solid it should be completely embedded in a cake of solid paraffin, 1in. thick above the wire everywhere.

They were then tested again.

		No. 1 coil.	No 2 (paraffined) coil.
Pint jars	A spark 2·0	1·054	1·074
	„ 1·5	·917	·906
	„ 2·5	1·25	1·25
Gallon jars	„ 1·5	1·03	1·03
	„ 2·0	1·26	1·26

Their equality is, as far as one can tell, absolutely undisturbed. The change of surrounding medium from air to paraffin makes no appreciable difference.

To see if a *conducting* covering would have much effect, the paraffined coil (which looked like a solid block of paraffin) was now coated all over with tinfoil, except just at the places where the terminals protruded. The following were now the B spark-lengths :—

——	No. 1 or uncovered coil.	No. 2 coil with tinfoil insulated.	No. 2 coil with tinfoil earthed.	No. 2 with tinfoil to one of the jars.
A spark 1·5	·906	·841	·828	...
A spark 2·0	1·048	·886	1·026	·884
A spark 2·5	1·258	1·104	1·098	...
Covered No. 2 up now in soldered tinplate, in addition to the tinfoil, except for the terminals.				
A spark 1·5	·860	·775	·775	...
A spark 2·0	1·068	·933	·935	...

Thus in this case there is a distinct though not very great diminution of the B spark caused by the surrounding metal, whether it be earthed or not. The armour-plated coil makes a *better* alternative path than the bare wire, a result which is natural enough.

(To be continued.)

Specific Resistance of Sulphur.—On page 254 of our last issue, the specific resistance of sulphur at 440° C. and at 350°C. is given as 7 7 and 56 5 megohms respectively; it should be 7·7 and 56·5.

THE PARIS EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT).

July 15, 1889.

One of the most creditable of the English exhibits is that of Messrs. Paterson and Cooper, who show a variety of electrical measuring instruments and appliances, amongst which are included the well-known permanent magnet ammeters and voltmeters of Ayrton and Perry, which this firm has manufactured since their first appearance. Messrs. Paterson and Cooper's ammeters and voltmeters constructed on the electromagnet principle are also shown. In these instruments, for the weak controlling force of an electro-magnet is substituted the powerful force of a spiral spring. In the case of ammeters, for currents of ordinary intensity the electro-magnet is wound with wire in the usual way, but for the measurement of large currents the wire is replaced by a single bar of copper 1½in. diameter, the magnet being in the form of a ring which nearly embraces the bar, leaving only a sufficient space between its open ends for the soft iron deflecting needle to lie in. (See *The Electrician*, December 7, p. 35, 1888.) Several Cardew voltmeters of the latest design are shown, as well as a Pocket Voltmeter about the size of an old-fashioned watch. A Thomson and Starling Universal Photometer for measuring candle-powers from half a candle to 10,000 candles, is also exhibited. In addition to these useful instruments, Messrs. Paterson and Cooper have an interesting collection of fittings and accessories connected with electric lighting. Amongst these, a polished slate tablet for a six-circuit distribution, on which are mounted the necessary switches, fuses and measuring instruments, is conspicuous.

Amongst the many excellent exhibits of Swiss electrical engineering firms that of MM. Cuénod, Sautter et Cie., of Geneva, is very prominent. This firm show several types of the Thury dynamo, Thury automatic current regulator, and Thury arc lamp. The Thury dynamo is a six-pole machine, with very small internal resistance, and running at a low speed. The table below gives some data respecting the speeds and outputs of these machines :—

Horse-power absorbed.	Power in Watts.	Revolutions per minute.	Weight in lbs.	Watts per lb.
41	27,500	450	4,400	6·2
57	38,500	450	5,500	7·0
81	55,000	450	6,600	8·3
81	55,000	250	9,900	5·5
115	77,000	350	9,900	7·7
185	125,000	185	13,200	9·5

The Thury Automatic Regulator can be used for constant-potential purposes, although it is generally employed to regulate the current of dynamos driven at varying speeds, and for other similar purposes. The apparatus is made of two types; in one, the necessary motive power is obtained either from the dynamo pulley or independently, in the other an electric motor is provided. In the first type the regulation of the current is effected by the switching in or out of resistances, the rheostat being provided with a large number of contacts to avoid sudden alterations in the current strength; in addition to which, the contact-switch is divided into two pieces insulated from one another, but connected through a resistance equal to the mean resistance between any pair of contacts, which device still further conduces to smooth working. The switch is carried on a horizontal axis, actuated by a wheel and tangential screw; this screw is itself actuated by two friction cones driven by means of cords, an arrangement which is strikingly similar to that found in Prof. Jamieson's Electric Governor. The friction cone shaft is capable of a longitudinal movement when the soft-iron disc at its extremity is attracted by the electro-magnets. When the disc is pulled towards the right-hand magnet, the movement of the shaft brings the left-hand cone into contact with a large friction wheel on the shaft of the tangential screw, thus causing a movement of the rheostat switch. If the left-hand electro-magnet is energised, the rheostat switch is in a similar manner moved in the reverse direction. The

Digitized by Google

magnets are brought into play by means of a solenoid, the core of which is connected to a small lever, which switches one or the other of the magnets into circuit as required. The terminals of the magnet coils are themselves carried on a movable lever, which is connected with the rheostat switch in such a manner that whenever it moves it immediately breaks the circuit of the magnet coils. By this device, over-regulation is guarded against, for when the current increases and the core of the solenoid brings one of the electro-magnets into play by moving the lever, the resulting movement of the rheostat switch immediately breaks the magnet coil circuit, which is only re-established should the current continue to increase. In practice this regulator proves very sensitive and quick in its action.

In the second type of regulator the current alone supplies the necessary motive-power. The two electro-magnets are dispensed with, and the lever of the solenoid reverses the direction of rotation of the motor.

Regulators of this description have been adopted to maintain a constant difference of potential at the terminals of the lamps in the Geneva Theatre. The current for this installation is obtained from the central station, and as the demand for current varies enormously it was found absolutely necessary to compensate for the losses in the leads by means of automatic regulators of the second type.

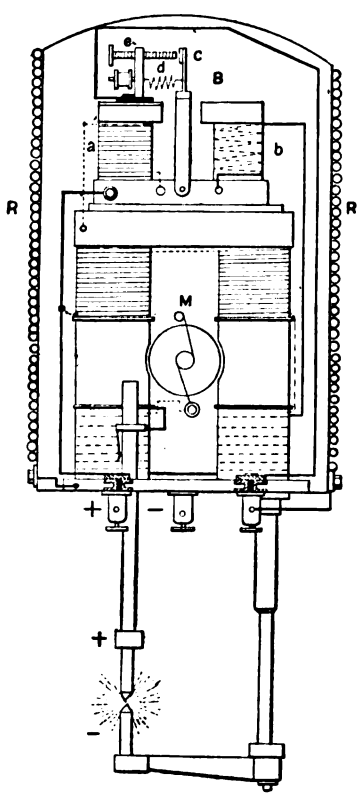

Fig. 1.

The Thury Arc Lamp (Fig. 1) is of the self-focussing motor type, and is, as a rule, wound differentially. The lamps are constructed to burn continuously for 14 hours and are provided with a by-path, B, containing a resistance, R, approximately equal to the normal working resistance of the lamp. In some cases the series coil is done away with, and the action of the shunt coil is strongly reinforced; the lamp can then be made to work on almost any circuit, provided, of course, that the size of the carbons is adapted to the particular strength of current employed. The motion of the carbons is caused by two motors, one an electric motor, M, the armature and magnets of which are a shunt to the arc, the other motor consisting simply of the lower carbon-holder and a counterpoise. The former brings about the approach of the carbons, the latter draws them apart. In the differential type, the lower portion of the magnets has a series winding, acting in opposition to the shunt coils. To prevent the carbons coming together too rapidly the armature of the motor is completely enclosed in a copper case so that racing is immediately checked by the generation of powerful Foucault currents. The two carbon-holders are mechanically connected by means of a series of toothed wheels, arranged so that the descent of the negative carbon causes the ascent of the positive carbon. The motor actuates the carbons by means of a large toothed wheel, and as the field magnets are chiefly energised by the shunt coils, it only acts when the carbons are apart, and the further they are apart the more powerful its action. In the differential lamps, of course, the motor only acts when action of the shunt coils overpowers that of the series coils. The by-path B consists of an electro-magnet, *a*, *b*, between the poles of which oscillates the armature *c*. The limb *a* is excited by the shunt-current, and the limb *b* by the main-current. A spiral spring, *d*, keeps the armature *c* against the screw-contact *e*, which is in communication with the resistance coils R, which are wound round the exterior of the lamp and connected to the negative terminal. At the moment when the current is started, the carbons are apart, the shunt coil *a*, therefore, acts with great effect, and keeps the armature *c* firmly against *e*, and the motor soon brings the carbons into contact. At this moment the series coil *b* of the by-path is traversed by a strong current, and the shunt coil *a* is deprived of current; the result being that the armature *c* is pulled away from *e*, breaking the by-path circuit. The lamp then works in the normal fashion. Whenever the difference of potential at the lamp terminals becomes dangerously high, the shunt coil *a* attracts the armature *c* and cuts the lamp out of circuit. The working of this lamp is said to be very satisfactory.

A good show is also made by another Swiss firm, Messrs. Brown and Co., of the Oerlikon Engineering Works, near Zürich, who exhibit a large number of dynamos for public lighting, ship lighting, and transmission of power purposes, together with arc lamps, switch-boards, and other accessories. This firm also have on their stand in the Palais des Machines several steam engines which have been specially designed for dynamo work. One of the most prominent exhibits is a 200 horse-power transmission of power plant. The generator and motor are of the usual Oerlikon type, with 4 poles, cylinder armature, and cast-iron field-magnets set radially, their outer extremities being connected by a very massive yoke, the lower half of which is cast in one with the bed-plate. The two machines are precisely similar, except that in winding the armature of the motor allowance has been made for the volts lost between it and the generator, in order that both machines may run at approximately the same speed. The armature of the generator is wound with 400 turns of 19 strand 1·3 millimetre copper cable, while that of the motor has only 368 turns. The commutator, which like every part of these machines is of most substantial construction, has 200 segments in the case of the generator and 184 in the case of the motor. The armature core in built up in the usual way of soft sheet-iron discs, 6 millimetres thick, separated by paper. The field-magnets are wound with copper sheet 1 millimetre thick and 300 millimetres wide, each limb being wound with 60 turns, and all four windings being in series with the armature. When running at 500 revolutions the generator has an output of 625 volts and 270 amperes (168 kilowatts), though these figures may safely be exceeded if necessary. The motor of the transmission plant drives the main shafting in the Swiss Section in the Palais des Machines. These dynamos, I may mention, are of the same type as those now at work at Schio (Italy) and Derendingen (Switzerland). The same firm also show a small transmission plant. The machines in this case are of the two-pole type, and the motor drives the shafting of the Swiss Section in the gallery. In addition they exhibit two steam engines, with dynamos coupled direct. One of these dynamos is a four-pole machine, with a series-wound drum armature and an output of 65 volts and 180 amperes. This particular type of dynamo is intended more especially for use on board ship, and is, therefore, what is commonly known as "ironclad," and has little or no external field. The other dynamo is a two-pole machine, with an output of 65 volts and 500 amperes, and is used to supply current to twenty-eight 8-ampere arc lamps lighting a part of the Swiss Section. These lamps, which are of remarkably simply design, I shall refer to later on.

Digitized by Google

The steam engines exhibited by the Oerlikon Engineering Works in connection with their dynamos are all of the vertical type, and comprise a 200 horse-power compound condensing engine, running at 180 revolutions and driving the generator of the transmission of power plant through belting; a 50 horse-power engine of similar type, running at 360 revolutions, and coupled to the arc-light dynamo, and a small single-cylinder engine, which runs at 480 revolutions, and drives the ironclad dynamo.

The chief feature of the Brown arc lamp is its great simplicity. In the generality of lamps the violent jerks caused by sudden variations in the resistance of the arc are modified by ingenious but complicated regulating devices. Mr. C. E. L. Brown has, however, dispensed with all regulating gear. It will probably be remembered by your readers that about this time last year, in a short note to *l'Electricien* (see *The Electrician*, August 10, 1888, p. 446), M. Hospitalier pointed out as a matter of common knowledge that arc lamps run off constant potential circuits regulate better the greater the distance in the

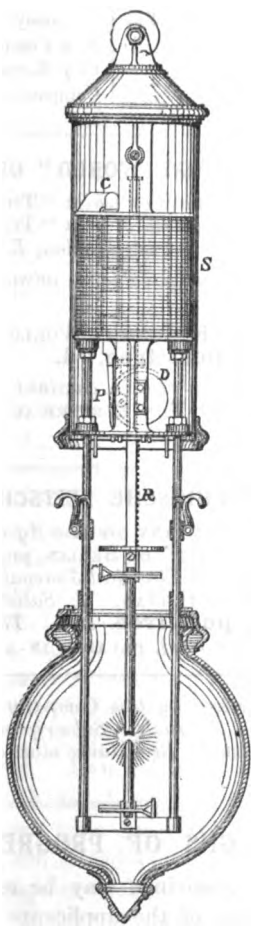

FIG. 2.

branch, and suggested that if we could use an electro-dynamometer (whose action is proportional to the square of the current) in lieu of an electro-magnet, we should increase the sensibility of the arrangement, and should be able to work satisfactorily with about 60 volts, instead of 80 or 100 at the dynamo terminals, and dispense with wasteful intercalated resistances. Mr. Brown has not indeed adopted the particular device suggested by M. Hospitalier, but he has nevertheless produced a lamp which works remarkably smoothly on a constant-potential circuit, without any intercalated resistance whatever, and with less than 50 volts at its terminals. In the Brown lamp the lower carbon is fixed, the upper carbon hanging from a rack, R (Fig. 2), gearing with a small pinion. On either side of this pinion, and upon the same axis, are two large, soft iron discs, D. Above these is the large solenoid S, and inside this is the iron core C, suspended from a spring, and capable of moving both vertically and laterally inside a brass cylinder, which forms an air dash-pot. The lower part, P, of the core is flattened out, and is a millimetre or two away from the rims of the iron discs. Between the face of the pole-shoe and the edges of the discs a thin layer of brass is interposed, which becomes thicker as it goes higher up the iron. The action of the lamp is as follows:—When the current passes, the core becomes magnetised and is simultaneously attracted upwards and against the iron discs, which consequently turn round and strike the arc. As the arc becomes longer the core slowly descends, and the carbons approach one another. At the same time the magnetism diminishes, and when the core has reached its middle position the smaller attractive power, acting through a greater thickness of brass, allows the discs to slip round slightly. In practice the working position of the core remains the same, and all feeding takes place by this slipping action. These lamps, as I have remarked above, are employed to light a part of the Swiss Section, so that their satisfactory working can be seen by any one visiting the Exhibition.

In addition to measuring instruments, the Oerlikon firm show an automatic safety apparatus, which short-circuits the magnet coils of a dynamo in case of dangerous excess of current. This automatic apparatus consists of a straight electro-magnet, having a long core. Beneath this core is an armature working on a hinge, and which in its position of rest holds up the end of a weighted lever, the lower extremity of which turns on an axle held in a frame. Beneath this lever are two parallel spring contacts, and as soon as the current attains a strength of about 20 per cent. above the normal, the armature is drawn upwards, the lever is released and falls between the two springs, short-circuiting the field-magnet coils. This device is fitted to the generator of the large transmission plant, while at both ends of the line there is a switch by which the circuit can be broken gradually whenever the necessity arises. In this switch the metallic contacts are broken first and the arc is then drawn out from a carbon contact, the arc being slowly lengthened until the breaking point is reached.

The exhibits of these two Swiss firms are of a very excellent order and do credit both to their enterprise and engineering capacity.

The huge ball given last week at the Palais de l'Industrie was the occasion of a very complete installation of the electric light. The methods employed to light the building were somewhat diverse. Two 300-light Edison dynamos connected in series, and regulated to give about 300 volts, supplied 250 Henrion or Pieper arc lamps arranged five in series. Across the dynamo terminals were placed three batteries each of 150 Philippart accumulators with a view of lightening the work of the machines. The larger part of the incandescent lamps were supplied by two 1,000 light Edison dynamos, but 1,600 lamps were run off transformers, the primaries of which were connected to the main running from the Edison station at the Palais Royal to the Élysée.

The jury for Class 62 (electricity) has at last been finally constituted. The president is M. Mascart; the vice-president, Mr. Preece; the reporter, M. Potier; and the secretary, M. Turettini. The jury is divided into four sections, as follows:—1st section: Dynamos, transformers, and measuring instruments—MM. Fribourg, Hering, Potier, Sciama, Turrettini. 2nd section: Telegraphy, telephony, electric signalling apparatus, cables, wires—MM. Aylmer, Marcel Deprez, Jousselin, Preece, Trottin. 3rd section: Electric lighting apparatus—M.M. Huet, Postel-Vinay, Rau, Rousseau, Sautter. 4th section: Electrochemistry, batteries, accumulators, bells, miscellaneous appliances—MM. Abdank, H. Fontaine, Gody, Mascart, Sebert. The jury will meet at 27, Avenue de Labourdonnais, and the different sections at the offices of Class 62.

The fact that there have been three slight fires in the Exhibition due to the electric light leads shows very clearly that the wiring is not what it ought to be, and it would certainly seem advisable to look more carefully to the insulation, if occurrences of this regretable character are in future to be avoided. The first two fires, which took place in the garden facing the Palais des Arts Libéraux and in the Palais des Machines respectively, were instantly extinguished. The third fire, which happened in the conduits running between the Palais des Machines and the Galeries des Industries Diverses, was not put out under half an hour.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

Subscriptions are received by this Company for all Continental and American Electrical Journals. Subscription Rates on application to "THE PUBLISHER." *Remittance must accompany order* IN ALL CASES.

SIGNS OF PROGRESS.

Although some misgivings may be reasonably entertained with regard to certain of the applicants who have joined the crowd of new Electric Lighting Companies now seeking Provisional Orders at the hands of the Board of Trade, the general effect is encouraging to the trade and reassuring to the public. Special interest, however, at this moment attaches to the established companies whose business prospects, based on actual experience, will afford some indications of what the new Undertakers have to expect. It happens that Reports relating to at least three well-known companies have just been issued, and that the contents afford information of a kind which at this juncture is much needed. Last in point of date, though not in importance, is the EDISON AND SWAN COMPANY'S annual report to be presented at the general meeting of shareholders on the 30th inst. They are to be congratulated on several grounds, for they have not only emerged victorious out of a series of legal conflicts, but have earned a handsome dividend which they are now in a position to distribute. This dividend, which is 7 per cent. on the A shares for the year ended 30th June, 1889, and 3 per cent

Digitized by Google

on account of arrears of preferential dividend in respect to the same period ended 1884, was anticipated at the last November meeting, but was held over because of the uncertainty which then prevailed as to the result of the appeal in the action against the Brush Company. Happily the threatened reference to the House of Lords has been abandoned by that Company, and an understanding arrived at which leaves the Edison Company in undisputed possession of their lamp patent, the taxed costs of the action being paid by the Brush Company. This result sets free the earnings of the successful litigant; and that they amount to a sum which enables such a dividend as we have named to be paid out of them is evidence of the soundness of the business in which the Edison Company is engaged. That business is now exclusively confined to the manufacture of lamps, fittings, and electrical apparatus; and although we may regret that the course of events has created a monopoly of lamp industry for the Edison Company, the fact that, notwithstanding the prices they are able to charge, their sales continue at an enormous and progressive rate is a further proof of the strides which electric lighting is making.

The ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION is the second of the companies on whose affairs we are able to comment, a report of its directors to be presented at an extraordinary general meeting to be held next Monday being now in our hands. Freeing itself from the costly proceedings referred to above, the Brush Company is about to make a new departure in view of its rapidly growing business and the demands that will be made upon it when the impending schemes for electric lighting throughout London and the provinces get fairly to work. It is stated that already the orders for the past half-year exceed those for the whole of the preceding year, which were considerably greater than for the year previous, and the directors have reasonable grounds for believing that the next half-year will be still more prosperous. This being the case, and the existing manufacturing premises being already far too small, a large addition to the Company's powers of production has been obtained by the acquisition of the "Falcon" Works at Loughborough, in Leicestershire, where the old engineering business will be carried on, in addition to the new electrical business which is to be brought into it.

In still another direction this Company has made a fresh move which will not unlikely be imitated by other companies similarly situated. A subsidiary company was formed in 1882 to work the Brush and Lane-Fox patents in the Australasian Colonies, and has acquired a peculiarly strong position both in those latitudes and in India and South Africa; but the operations of the Company itself as well as of the parent company have been hampered by the undertakings entered into between them; and it is now seen that an amalgamation will be advantageous to both. This it is proposed to effect, and the necessary readjustment of capital consequent upon the amalgamation and the "Falcon" purchase scheme will be submitted for the approval of the Anglo-American Brush Company's shareholders at the forthcoming meeting. A call of £1 per share will be made in respect of the 25,511 £5 shares on which only £4 has yet been paid up; but with this exception no fresh strain will be put upon the shareholders, the purchase and amalgamation projects being arranged on the basis of payment in shares of the new Company to be created by the union of the three. The ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION will, it is proposed, be known in future as the BRUSH ELECTRICAL ENGINEERING COMPANY, a change of title which we think will be more in accordance with facts, as well as more agreeable to the Company's customers.

Of the LONDON ELECTRIC SUPPLY CORPORATION, whose report, which is represented by a well-drawn-up balance-sheet, was presented at the meeting on Monday last, we need say very little. A full account of the proceedings is published in our present issue, and it will be seen that the outlook for this Company is not less promising than that of the companies already referred to. The history of the undertaking, however, is different, and perhaps more instructive. The other two are manufacturing companies, whereas this is an electrical supply company. Known for some time briefly as the Grosvenor Company, it was worked as a private or semi-private affair, and, it is confidently asserted, at very considerable profit to the proprietors. When the schemes for lighting the metropolis begun to take shape naturally this highly-successful company was coveted as a nucleus for one of the most profitable businesses to be absorbed; but eventually the Grosvenor Company became the LONDON ELECTRIC SUPPLY CORPORATION, with its extensive works at Deptford, the Grosvenor's plant keeping the business going until the new works are sufficiently matured to do the whole business. Even as matters stand, the accounts of the Corporation show a small balance on the right side; and the areas assigned to it, we need hardly say, are some of the best in the Metropolis. Its balance-sheet is a model of clearness, and is calculated to inspire confidence in the minds of the shareholders, as well as of the general public who examine such documents emanating from electric lighting companies with a suspicion perhaps not wholly undeserved. Altogether a review of the position of the three companies here commented upon will satisfy any impartial observer that the electric light has made and is making progress at a rate with which we have every reason to be satisfied.

AN ELEMENTARY ANALYSIS OF THE GENERATION OF CURRENT AND POTENTIAL DIFFERENCE IN DRUM ARMATURE WINDING.

BY F. M. WEYMOUTH.

Events frequently march with a rapidity that all are not able to keep up with. Hence there are those who sometimes find themselves behind the times. This is especially the case with inventions of all kinds. It is not possible to follow up closely the periodical growth of many inventions, and to keep well abreast with the theory that may be involved in them. And all this applies not less to the growth and development of electrical science and machinery than in any other direction—in fact, we might say it especially applies to electrical matters. Thus, regarding the subject in this light, and in view of the fact that since the lapse of the Siemens' patent for drum winding this form of winding has come largely into use, it has appeared to us that it might be of interest to many if we were to conduct a species of investigation into this form of winding, having particular regard to the manner in which the current and potential difference are generated and the torque set up.

It may be well, however, first to consider briefly what are the more essential advantages that this method of laying the conductors on an armature possesses over the Gramme winding it is now to so great an extent superseding. Some of these are more or less obvious. It offers the whole area within the limits of the periphery and ends of the drum for the passage of lines of magnetic induction, as compared with the portion only of this total area offered by the Gramme ring type. Hence, other things being equal, for any given length and diameter of core, the drum will give the larger output; and conversely, for any given output, the drum armature, and with it the whole machine, can be made smaller, and so cost less than the other type. A greater radial depth of iron also can be got into the core, still further favouring the passage of lines of magnetic induction—a point of great moment. Economy in copper is also promoted, inasmuch as there is less length of conductor, as compared with

Digitized by Google

the Gramme type, owing to the absence of the interior parallel conductors that exist with the latter. This consideration is, however, much affected by design, a question it is not our present object to discuss.

The accompanying diagrammatic sketch represents in isometric perspective the drum-winding of an armature with commutator, but without spindle or core, except that the last-named is indicated by two lightly-dotted circles. A winding of eight turns only is depicted, so that all parts may be visible, and the commutator is shown an abnormal distance from the core to avoid the complication of its covering the cross-connections behind it. This sketch represents in essence what is the more modern method of arranging the windings, particularly for heavy currents. In the earlier drum armatures, such as those of Siemens and Edison, it was the custom to connect up the different sections, not one after the other, in order round the periphery of the core, but variously. This disorder of connection had the effect of preventing the attainment of a minimum difference of potential between neighbouring commutator segments, so that sparking at the brushes was not diminished as much as might be. But for constructional reasons also it is now more customary to effect the joining up, as here shown, one section after another in regular order round the armature. To assist the eye in following up the connections, the parallel

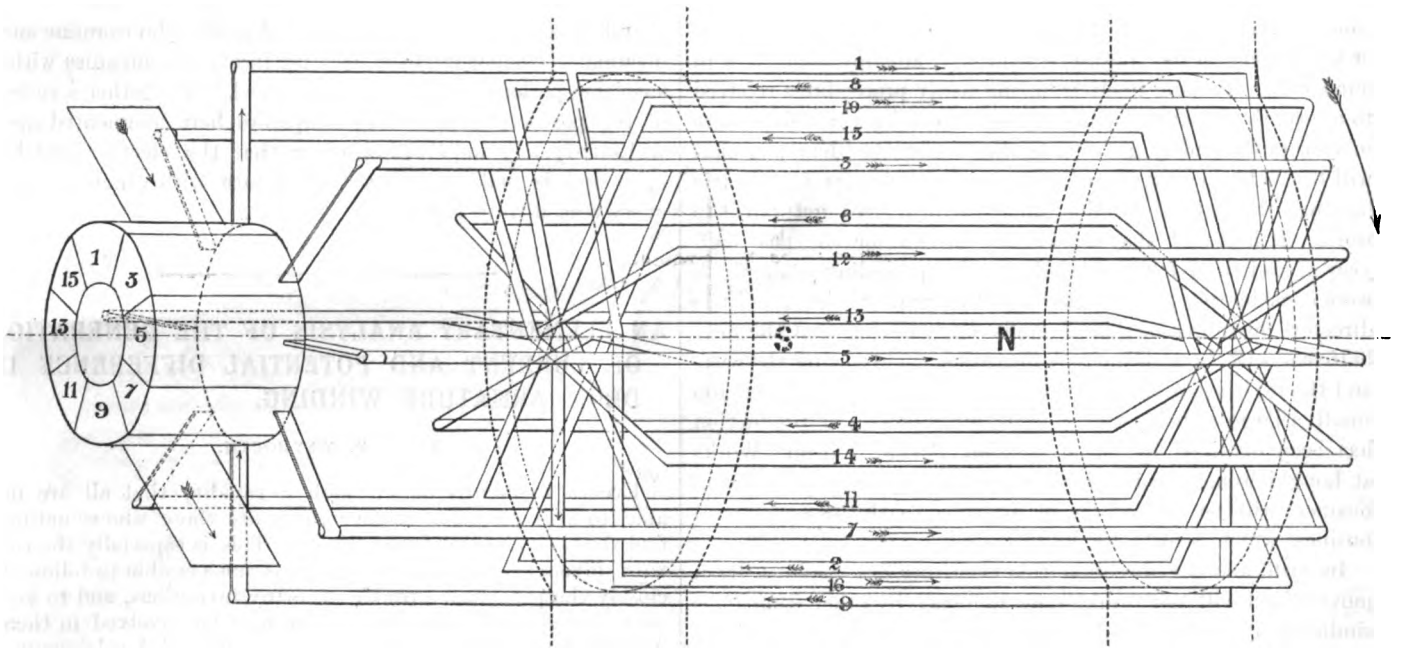

Diagram of a Drum Armature Winding.

conductor-bars are here numbered in the order of their connection. No. 1, for instance, is joined at the right-hand end to No. 2, and No. 2 at the commutator end to No. 3, and so on till No. 16 is united at the commutator end to No. 1 again. The bars with odd numbers alone, it will be observed, are extended to the commutator lugs. Each odd-numbered bar, and an even-numbered bar nearly opposite, with their end connections, form a section of one turn, the end of each section being joined up behind the commutator to the neighbouring odd-numbered bar, and not to its own. An endless circuit is thus formed round the armature, connected up at eight different points, corresponding to the eight sections, to eight several insulated commutator segments. Sometimes two turns per section are put in; only this, with conductors for heavy currents involves a double series of end connections, which, according to design, may add considerably to the total length of the armature and increase the percentage of inactive copper—that is, of copper not actually cutting lines of induction, and producing electromotive force. This latter reflection, indeed, bears on all copper projecting at either end beyond the core, which is, of course, confined within the limits of the length of the shorter even-numbered parallel bars. For many turns per section of wire for small currents it may be necessary to resort to the old Siemens' method of wrapping round the ends, or to modifications of other arrangements.

The armature in our illustration is represented as revolving in the field between two pole-pieces, shown by the heavy dotted lines, the back one of which is south and the front north, as indicated by the large S and N, and turning in the direction of the curved arrow. The lines of force, or magnetic induction, will, therefore, be going from the front towards the back, though with a normal distribution more dense toward the top and bottom, where the poles are closer, than in the middle. This latter inequality, however, is of course much modified by the iron of the core. Each section of the winding will form a loop or circuit revolving in this field, and when in a vertical position, such as section 1—16 nearly occupies, will enclose a maximum number of lines, as compared with none at all when lying horizontal. Revolving in this field, an electro-motive force will be generated in the conductors.

Firstly, now to consider the direction of the current, weknow that according to the law discovered by Faraday, when a circuit revolves in a field such as here represented, the direction of the current will depend on two things, namely, according to which side of the loop the induction lines enter, and as to whether, during the revolution, the number of these lines is increasing or diminishing. If the loop revolves so that when the lines are diminishing in number they enter on the side towards which the top bar approaches, then, as viewed from this side, the current will run from left to right in the top bar, and round again from right to left in the lower bar. This is the condition in our illustration, where the point of view, N, is at the front. Now, it is obvious that during one revolution there are four different times when the conditions change. The circle of the revolution of the armature may be divided into four quadrants, defined approximately by the vertical and horizontal centre lines. The four times of change are thus those instants in which any bar of a section passes successively from each of these quadrants to the next. There is a difference, however, between the conditions at two of these instants as compared with the other two. When a given bar at the top passes from a quadrant on one side of the vertical to that on the other side and back again at the bottom, only one change takes place at each of these two instants, namely, that the enclosed lines of force that were increasing in number as the bar approached the top (or bottom) will now be decreasing in number. But at the two instants when the loop is about horizontal and one given bar passes from an upper quadrant to the one below and rises again on the other side, *two* changes take place at each of these in-

Digitized by Google

stants. Firstly, the number of induction lines that were decreasing in number to zero will now commence to increase again; and secondly, whereas the lines had been entering the loop on the one side, they will now commence to enter on the *other* side. It hence arises that when passing the vertical position, where there is only one change of condition, this change reverses the direction of the current round the section. But when passing the horizontal position the one change from excluding to including lines of induction is simultaneously cancelled by these lines commencing to enter on the other side of the loop; hence the current is not reversed at these latter two instants. The aggregate result, therefore, is that the current is reversed only as each section passes the vertical (approximately), and is always running from right to left on one side of the armature and from left to right on the other side. Thus, in our sketch, the direction of the current is to the right in front and to the left at the back, as indicated by small arrows, while those sections which are nearly vertical, namely, 1—16 and 9—8, are neutral. This approximately vertical plane is, of course, what is known as the plane of commutation, though we shall refer to this again further on.

We have dealt so far with the direction of the current merely. We have now, however, to consider the rise of the "electromotive force," or "E.M.F.," or "potential," as it is variously termed, and without which there would be no current. This, as is well known, is proportionate to the maximum number of lines of force passing through the section, or loop, and the speed of the revolutions. The field may be small and intense, or large and weak. Regarded more intimately as to the speed, the potential varies according to the *rate* at which the magnetic lines are included or excluded by the section. Now, as in the case before us, when these lines run horizontally, it is palpable that when the section is about vertical, the *rate* at which it is including or excluding lines is scarcely more than nominal, as the revolution through a small arc at the top or bottom makes little difference in this respect. Hence the E.M.F. generated here passes through zero value. When nearly or about horizontal, the reverse hold good, as the section is in the most advantageous position for this purpose, and excludes and includes the lines as it respectively approaches and leaves the horizontal at its maximum *rate*. Hence the maximum E.M.F. is gathered when the sections are about horizontal; but potential is also being generated in the intermediate sections between the horizontal and vertical. Theoretically, the E.M.F. generated in any one of these varies not with the angle but with the sine of the angle which its plane makes with the vertical plane; or, in other words, varies directly with the horizontal distance of its bars from the central vertical plane, similarly as the number of lines of induction enclosed varies with the vertical distance of the bars from the horizontal plane. It must be clearly understood that the foregoing refers only to the *generation* of the potential in each several section, as the potential difference that may actually exist in any section at any instant may be very different from that which it is itself at that instant generating. We may now consider the course of the current round the winding, together with its accumulation of E.M.F., and its delivery to and return from the outer circuit. Referring to our sketch once more, it will be observed that the brushes touch on the segments of the commutator connected to bars 1 and 9. To commence with bar No. 1, we immediately remark that this being in connection with the upper brush, and the current in it running from left to right, the current from the outer circuit will here be entering, and the upper brush will be the negative brush of the machine. In this bar 1 there will be the minimum potential difference, and from its approximately vertical position it can generate practically none. The current running to the right passes across the end to bar 2, thence to the left and across again to bar 3, accumulating E.M.F., and so through sections 4—5, 5—6, where it practically gets its greatest amount of E.M.F., through 7—8, and to the left-hand end of bar 9. This latter being connected to the segment whereon the lower brush makes contact, the current will here pass to the outer circuit, and this brush will form the positive pole of the machine. But the total current and potential difference here, it will be observed, are what has been accumulated in the sections represented by bars 3, 5, and 7 only; and these form but half the winding, not counting neutral sections. We have now to account for the other half. Returning to bar 1 again, this, with bar 16, forms a section about vertical, and consequently neutral. The right-hand end of this latter bar (16), however, is connected across to bar 15 on the further side, where the current is in all cases running from right to left. Hence, whereas one half of the incoming current passed along the length of bar 1 and so to bar 2, the other half will cross to bar 16 at the commutator end, and thence into the series of sections 15—14, 13—12, 11—10, gathering potential difference on its way, on to the right-hand end of bar 9, and so to the lower brush, together with the current entering that bar at its left-hand end. Thus the current, entering at the left end of bar 1, has two paths in parallel which it may follow throughout the two series of sections which alternate with one another round the armature to reach the positive brush; but the potential accumulated in each of these series is the same. Hence, as when two pipes of similar diameter delivering water at the same head (or pressure) unite in one common pipe, the pressure may remain the same, but does not increase, while the amount of water delivered, or the current, is doubled, so the current delivered at the lower brush is equal to the currents of both series of sections added together, or twice that of one of them, while the electromotive force is not doubled, but remains only such as is accumulated in either one of the series. Hence, in calculating out a drum winding it is requisite to obtain the total area enclosed by the several sections of one series only to ascertain the electromotive force, while the section of the bars need be only half that necessary to carry the whole current of the machine. It will be observed here, in accordance with a remark we have already made, how that although there will be little or no potential difference *generated* in sections 9—8, 9—10, yet the potential difference actually existing in these is the aggregate potential of the series to which they each belong. It may appear paradoxical that in the case of the second series the potential difference should be rising on its way down the further side in bars 15, 13, 11, and correspondingly up the front side, in a contrary direction to that in which the armature revolves; but this is the way the current goes in this series of sections, and it naturally forms its "head," or point of highest potential, at the end towards which it is tending.

We have thus far shown how the E.M.F. and current are induced. There are yet some further points in this connection to be referred to. The first which may be mentioned is one of no little importance. It will be remembered that the long bars down the sides of the armature have an increasing potential in their order from top to bottom; consequently and inversely, their respective short bars opposite have a potential increasing from bottom to top. It follows that in all cases where the sections are about horizontal, the currents in their respective parallel bars on both sides are of about the same potential; but at the top the short bars of the high potential come alternately with the long bars of low potential, and *vice versâ* at the bottom, the differences of potential increasing gradually from the sides toward the top and bottom, till at these latter points bars of maximum and minimum potential are lying adjacent. This constitutes an inherent evil of drum winding which cannot be eliminated. Another point to which attention may be drawn concerns the brushes. Should these be slipped round so as to come on the segments of the commutator 7 and 15, instead of 9 and 1, it might appear at first sight as though the current would be reversed in the outer circuit. But it would not be so, as the current would be reversed in bars 8 and 7, and 15 and 16, instead. In other words, the sections to which bars 7 and 15 belong would for the time become neutral, and the current continue to flow out at the lower brush, inasmuch as the pressure or potential in 7 is higher than that in 15. But as according to the principle already enunciated, whereby the highest potential must be at the bottom of the vertical plane of commutation, the effect of moving the lower brush on to 7 is simply to take it from a place of higher potential to that of a lower. Moving the brushes of course to points on the commutator other than of the maximum and minimum potential will reduce the E.M.F. in the outer circuit, the potential difference in the latter

Digitized by Google

being in any case less than that in the armature, as otherwise there would be no flow of current into it.

We have, when mentioning the plane of commutation, alluded to this as only approximately vertical. It is in this connection that the polarisation of the iron core of the drum may now be considered. According to Ampère's well-known rule, the direction of the current round the horizontal sections of the winding will induce a north pole at the top of the core and a south pole at the bottom. With regard to the sections more nearly vertical, we may assume the plane of commutation to be exactly vertical, and so the bars 1 and 9 in our illustration to be exactly at the top and bottom respectively. We then observe that section 10—9 tends to produce a north pole on the *further* side of the core, while section 15—16 tends to produce a north pole on the *front* side; hence these two tendencies counteract each other. Intermediate sections, however, such as 11—10, 15—14, will tend to produce a north pole, the one on the further side of the top and the other on the nearer side. Hence the ultimate result will be a broadening of the poles at the top and bottom. But the effect of the magnets between whose pole-pieces the armature revolves is to induce poles at the *sides* of the armature, a north-pole on the further side and a south pole on the front, at right angles to the self-polarisation of the armature. Experience has shown that it is desirable to magnify this effect, and to make the enclosing magnets so powerful that they shall almost entirely overcome the self-polarisation of the armature. Hence ultimately, by a compromise, the north pole of the core becomes located a little above the horizontal on the further side next the S pole-piece, and the south pole of the core a little below the horizontal on the front side opposed to the N pole-piece. Thus the plane of polarisation of the core is a little tilted, and the lines of magnetic induction not quite horizontal, and the plane of commutation, as already explained, being at right angles to those, becomes a little out of the vertical, determining the lead of the brushes. The torque, or tangential pull on the drum, is of course represented by the attraction between the poles of the core and the contrary poles of the magnets to which they are respectively opposed, requiring power to overcome it.

THE SPRAGUE IMPROVED ELECTRIC RAILWAY MOTOR.*

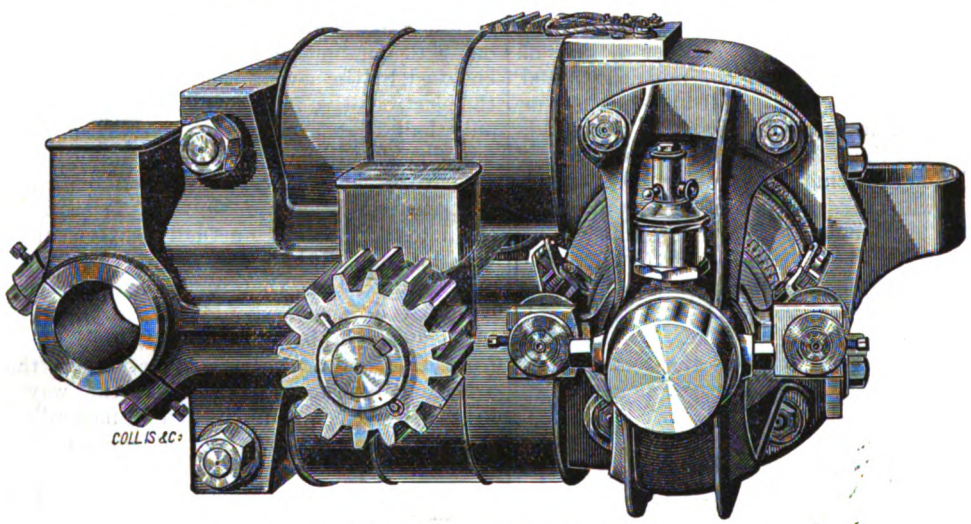

FIG. 1.—New Sprague Electric Railway Motor.

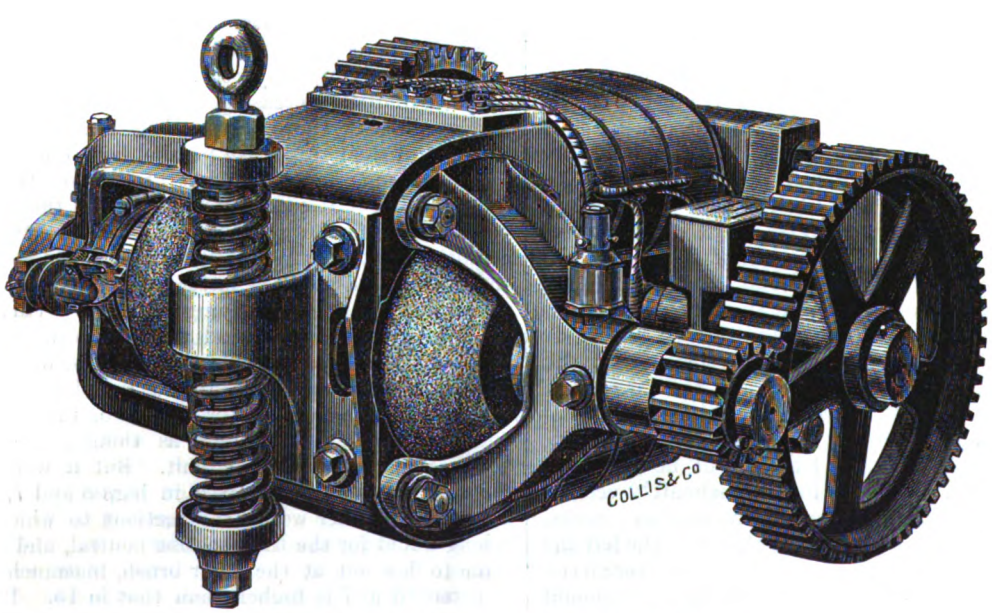

FIG. 2.—New Sprague Electric Railway Motor.

We publish in this issue two views, Figs. 1 and 2, of the Sprague improved electric motor for street railway work. Only one intermediate shaft is used between the armature pinion and the main gear, and the entire reduction is about 12 to 1. The main gears are of the split-gear pattern, so that in case of necessity they can be easily removed from the shaft without dismounting the machine. The pinion and all the bearings are also constructed so that they can be independently removed, if necessary. All the bearings are made as simple as possible and protected from the

* From the *Electrical World* of New York.

Digitized by Google

weather by dust guards. The armatures are of the type which has been proved to be water-proof and incapable of injury by moisture. In a recent test upon one of these armatures, made at the Sprague factory at Schenectady, it was placed in a tub of fresh water and allowed to remain there for twenty-four hours, and then in a tub of salt water and once more submerged for the same time. After each of these baths the armature was placed in position in the motor and the machine was worked to one-third above its normal load, as measured by a dynamometer, for several hours without developing any trouble whatever. Another important improvement which has been adopted in this machine is that the field-magnet coils are completely incased, as shown in the engraving, a plan which fully protects the wire from all outside damage. These casings are hermetically closed, so that it is impossible for any moisture to affect the coils in any way. Besides acting as protectors against any moisture, these casings also have an important electrical action in protecting the coils, since, being made of copper, by inductive action they reduce to insignificance whatever extra current might be generated in the coils upon breaking the circuit. The regular Sprague graphite brush is used upon these motors, which has been shown to give such excellent results in this kind of work. The graphite, instead of cutting the surface of the commutator, as brushes made of copper and other materials have been proved to do, acts as a lubricant, keeping the commutator smooth, at the same time giving very good electrical connection. The method of flexibly suspending the motors, which is an original and very important feature of the Sprague system of railway work, and the method of starting, stopping and graduating the speed of the motor without the use of any wasteful resistance, is in use upon all the roads installed by the Sprague Electric Railway and Motor Company. A great deal of attention has been paid in the design of this motor to the matter of reducing the weight to a minimum while paying sufficient attention to durability and strength. With this object in view, cast iron has been dispensed with entirely in the magnetic circuit, and wrought iron substituted; the increased cost of this substitution is more than made up for in the increased efficiency obtained with the same weight.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 6, 1889.

An interesting article is published this month in the *North American Review* by Prof. R. T. Ely, one of our leading political economists, on the telegraph monopoly, advocating that the telegraphs should be turned over to the Government, for the reason that they constitute a natural monopoly, and should be controlled by the State, the only alternative being a private monopoly. Prof. Ely is known as a political economist of the Socialistic order, who believes that the State should own and operate such institutions as the railroads and telegraphs, as well as the post offices, while local communities should own and operate such things as waterworks, street car lines, gas works, and electric light plants. Some few months ago he appeared in print with regard to the advantages to be derived by a community from the operation of its own electric light plant, but the mistakes in his figures were at once pointed out by many of the practical men in the business, and the arguments that Prof. Ely offered are still wanting in a solid basis of fact. With regard to the telegraph question, Prof. Ely holds that there is no middle ground between the two alternatives of a private monopoly and a public monopoly, and as private monopolies are contrary to the spirit of American and English laws and institutions, the owners of the telegraph system must be compelled to relinquish their property and to hand it over to the Government to be operated as a public monopoly. With regard to the modern idea that such institutions as railroads and telegraphs can be left in private hands but may be subjected to Government regulation, Prof. Ely remarks that this means the interference of the Government in private affairs, complicating the Government functions, and opening the flood-gates of corruption. For these reasons he desires Government monopoly of the telegraph business, and thinks it desirable that our Government should purchase existing lines rather than compete with other lines. It follows, therefore, and, in fact, Prof. Ely admits as much, that the Government must not only buy the Western Union and Postal Telegraph Companies' lines and those of pretty well a hundred railroad companies, but must buy up the American Bell Telephone Company, the District Messenger Companies, and the Ticker Services. The Government must in fact go further than this, for Prof. Ely advocates a world telegraph union "that will be another one of those bonds which unite nations and make for national peace." Thus it appears the Government must also buy the Submarine Cables. Just how much money this represents it would be hard to say, but if we figure the telegraph systems of the country at $100,000,000, and the telephone at at least as much, it will be seen that not less than $250,000,000 would be required at the outset in order to enable the Government to follow the example of European countries. Prof. Ely does not think that this addition to the number of public employés would be in any sense a national danger, but holds, on the contrary, that it would at once tend to purify politics, and that the politicians of the country, finding themselves endowed with the disposal of several thousand new offices, would at once call for a most rigid and pure Civil Service system. It is to be feared that Prof. Ely is either of a very sanguine temperament, or else knows very little of "practical politics." As to the effect on the telegraph service of passing from private to public hands, Prof. Ely is of opinion that it would be a material improvement. Most Americans who go abroad have very little to say in favour of the Government telegraphs as they find them in Europe, but Prof. Ely cites one or two personal experiences to show that things are better managed in Europe telegraphically than they are here. Just at the present minute it cannot be said that the question thus agitated again by Prof. Ely is a burning one, but as it has been vigorously discussed before in Congress it may come up again at no distant date. In the meantime it is interesting to note the opinion of one of the Republican leaders, Mr. Chauncey M. Depew, who in an oration before the Law School at Yale, last week, expressed views decidedly opposite to those advocated by Prof. Ely. "The magnitude of modern enterprises," he says, "and the close competitions of business have rendered the massing of the money of the many into one company a necessity which seems to be steadily increasing. The only other suggestion for carrying on the great affairs essential to comfortable living in our complex civilisation is for the Government to conduct them all. But experience has demonstrated that then, as in the German railways, the people get the minimum of service for the maximum of price, and an army of office-holders keeps its party in power and prevents the reform of abuses or the remedy of wrongs. We meet the question better by a compromise, which may be wisely enlarged, of State and national supervision. That the Government should watch the management and bring it to frequent accountability, that it should firmly protect the public, the stockholder and the employés, is the present, if imperfect, solution of the corporation problem." I may say that as far as my own observation extends Mr. Depew's views have public endorsement, and that it is in this direction of Governmental supervision that the question will be settled.

Everybody, of course, admits the fact that there is at the present time a marked tendency towards concentration and consolidation of allied interests, and examples are to be found in the electrical field just as readily as there are in any other. Thus, for example, we have recently seen a combination in one large corporation of all the various Edison electric light interests. We now see a movement on foot for the consolidation of the various Westinghouse interests under one general management, to be known as the Westinghouse Electric and Manufacturing Company. It is stated that a proposition to this effect was made about the middle of last month, and that it came up again for consideration at the meeting of the Westinghouse Company held on June 27. The various electrical interests that will be affected are already large, owing to the phenomenally rapid growth of the Westinghouse Company and its absorption of various systems one after the other. There seems no reason to doubt that when all the affairs are subject to one management even greater progress will be made.

One of the subordinate Westinghouse companies is the Tesla, and I am inclined to think that in securing the services of such

Digitized by Google

a bright electrician as Mr. Nikola Tesla, Mr. Westinghouse displayed more than his usual shrewdness and foresight. The Tesla motor, which was brought out last year, and was the subject of a remarkable Paper read before the American Institute of Electrical Engineers by Mr. Tesla himself, has already been illustrated and described in your columns from time to time. Mr Tesla is still working away at the general problem, and seems destined to reach remarkable and valuable results before he "gets through." It is well known that one of the difficulties in alternating-current motor work has been to secure some means for bringing the motor up to synchronism with the generator before the alternating-current from the generator can be applied to drive it. In order to effect the starting of the alternating motor, and bring it to synchronism without external aid, Mr. Tesla has now devised a simple system, in which he uses an earth return during the period of starting only, For this purpose he constructs a generator with two coils or sets of coils, and a motor with corresponding energising coils. By means of two line wires one terminal of each generator coil is connected to one terminal of its corresponding motor coil, while the opposite terminals of the generator coils are joined together, and those of the motor also. For starting the motor an electrical circuit is temporarily established between the points of connection of the coils in the generator and motor, so that the system becomes an ordinary double-circuit one. When by this plan the motor has attained the desired speed, the earth connection is severed, by which means the system becomes an ordinary single-circuit synchronising one. I may add that it is reported from Pittsburg, where naturally questions connected with alternating-current motors have unusual interest, that it is proposed to have an alternating motor car in operation this fall, and that great advantages will be gained by dispensing with the commutator and its attendant troubles.

An interesting Paper was read last week at the closing meeting of the season of the American Institute of Electrical Engineers, by Mr. Leo Daft, with regard to work that he has been doing on the New York elevated roads, and some of the results that he has obtained with regard to the question of fuel consumption. So much has been said and printed during the last three or four years with regard to the Daft system of electric propulsion, that Mr. Daft wisely took it for granted that his hearers would be familiar with the details of the system, and he did not therefore enter upon them except to mention that he still adhered, as the result of his work, to the opinion that it would be better to run the train by a single locomotive, as on steam roads, than to adopt the practice of putting one or two motors under each car and dispensing with the locomotive altogether. Mr. Daft also was at some pains to emphasise his belief in the superior tractive effect obtained from the passage of the current between the wheel of the electric locomotive and the track, and he holds that the increased traction is equal to at least 30 per cent., and he has often seen as high as 35 per cent. increase. He says, moreover, that the tractive efficiency of electric locomotives is higher than that of ordinary locomotives for mechanical reasons. With regard to the question of coal consumption, into which Mr. Daft entered very fully, illustrating the points made by numerous diagrams, it would appear that a marked increase of service would be obtained by the use of electric motors, with a coal consumption of not more than one-half that of the steam locomotives now in service on the elevated roads.

Turning from the important question of the successful operation of the elevated roads by electricity, we find that great strides are now being made in the improvement of apparatus intended for the electrical operation of the street railroad. The Sprague Electric Company have just published illustrations and descriptions of their new motor for street railway work.* It certainly appears to be about as compact, solid, and effective a piece of machinery as it is possible to devise at this stage of the art, and one from which any amount of good work may be confidently expected. These machines are already in use on the Sprague roads at Cincinnati, Cleveland, Atlantic City, and elsewhere, and are doing excellent work.

[* An illustrated description of this new motor will be found in another column.—Ed. *E.*]

The electric light companies of this city are now filing their bids for street work. About a month ago these bids were first sent in, but Mayor Grant kicked, with his usual affability, because the companies desired to charge more for the service in the subway districts than they did for that in districts where they could operate by wires and poles. The new bids average from 25 to 30 cents for lamps of 2,000 candle-power in overhead districts, and from 45 to 70 cents for lamps in subway districts. It remains to be seen whether these revised bids will meet with any more favour than the last. It will be noted that the companies remain firm in their intention to collect more money for lamps fed through the subways, and in view of the high charge made for the use of the subways the rate offered by the local companies is not at all out of the way.

It is interesting to note that a general order has just been issued by the Army Department to the effect that the American Morse code will hereafter be used by the army for all purposes of signalling, whether visual or acoustic. The use of the English Morse, or Continental code, is to be discontinued. This action, it appears, is taken on the recommendation of the chief signalling officer, who desires to simplify signalling instruction, and to be able to avail himself readily in war time for signalling of civilian telegraphers. While it is admitted that fewer errors are likely to occur in the use of the English Morse, it is considered that that system is slower than the American, and that its continued use, moreover, would involve the employment of specially-trained experts, whose numbers could not be increased in a hurry if desired.

CORRESPONDENCE.

HOURS OF LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have read Mr. Wright's letter in reply to my inquiry about lighting hours, and circumstances in America must be widely different from those existing here if practice confirms the statements he has made.

First, I do not know what are the circumstances which cause so large a consumption during the day time, and next, I cannot understand how a large proportion of "business lighting" should increase the number of lighting hours instead of diminishing it, as such hours are shorter than those necessary for shops (except public-houses and hotels), and for all manufactories, except the very few who have to work all night.

With us, where the early closing system is in operation, the business hours of ordinary shops are very short. All the principal shops which employ a number of lights, and most of the smaller ones, are closed at 6 p.m., except on Saturday nights, when they remain open until from 7 to 9 p.m. I annex the number of hours under the circumstances, taking the average hour of closing on Saturdays as 8 p.m. :—

Lady Day quarter	114
Midsummer ditto	5
Michaelmas ditto	13
Christmas ditto	174
	106

If we make some allowance for lighting and extinguishing, 400 hours would cover the time of lighting.

In manufactories opening at 6 and closing at 6, the hours are :—

Lady Day quarter	174
Midsummer ditto	0
Michaelmas ditto	0
Christmas ditto	296
	470

or say 500 hours per annum. Average of both say 450 hours, so that in the case above given the "business" hours for lighting are shorter than those for domestic consumption, which counting only from dusk up to 10 o'clock, are 1,443, and to 11 o'clock 1,808. These latter hours embrace Sundays, which are excluded from the other schemes of lighting.

Of course in London hours are later in the shops, and allowing 7 o'clock for ordinary shops this would add about 200 hours

Digitized by Google

to the annual consumption. I exclude hotels, &c., and there is a considerable day consumption in the Metropolis.

Now the effect of these figures is this, that a large amount of business, as compared with domestic consumption, would reduce instead of increasing the number of hours, and I am satisfied that your estimate of 700 to 800 hours founded on actual practice in this country is a liberal one.

I would require some fuller explanation than any Mr. Wright has given before I can see my way in an estimate of 2,095 hours per annum as an average.—Yours, &c.,

Cork, July 13th, 1889. DENNY LANE.

THE MAGNETIC PROPERTIES OF IRON AND NICKEL ALLOYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—I have recently been making some experiments on the magnetic properties of an alloy of iron and nickel. A statement of the result may be of interest to some of your readers. I am informed by Mr. Riley of the Steel Company of Scotland, who gave me the sample I have used, that it contains 24·5 per cent. of nickel and 0·85 per cent. of manganese. It proves to be almost non-magnetic, its permeability being only 1·4, much the same as that of manganese steel. On heating a block of the metal to a high temperature and allowing it to cool, and noting the temperatures at successive times, it is found that the curve expressing the relation between temperature and time exhibits no disturbance such as I have observed with wrought iron and steel. The non-magnetic properties of this material are very remarkable, both iron and nickel being strongly magnetic.—Yours, &c., J. HOPKINSON.

5, Victoria-street, S.W., July 15, 1889.

THE LONDON COUNTY COUNCIL AND THE METROPOLITAN ELECTRIC LIGHTING SCHEMES.

At the meeting of the London County Council last week, the following letter was read from the Board of Trade :—

"Board of Trade (Railway Department),
London, S.W., July 1st, 1889.

SIR,—I am desired by the Board of Trade to forward to you, for the information of the London County Council, copies of Provisional Orders which the Board of Trade have granted in the Metropolitan area under the Electric Lighting Acts, 1882 and 1888.

The County Council will observe that the provisions of the Orders vary in some particulars from the provisions contained in the Model Order, of which a copy was forwarded to you on the 12th ultimo (R 8,604).

Modifications have been introduced in consequence of representations made to the Board of Trade since the preparation of the Model Order.

In adopting them, the Board of Trade have had especial regard to the suggestions made by the Committee of the London County Council, with whom the Board of Trade have had the pleasure of discussing the subject, and clauses have been framed with the object, as far as possible, of giving effect to those suggestions.

It will be seen that a section has been introduced exempting from the powers of the Undertakers interference with embankments, parks, or open spaces, not forming part of any street vested in the London County Council.

The Committee were desirous that the public bridges vested in the Council should be included in this section; but no power is conferred by the Order to interfere with any portion of a public bridge other than the roadway over it, and the Board of Trade are of opinion that the provisions of sections 13 and 15 will sufficiently prevent any works likely to be detrimental to a bridge, and that, in this respect, a roadway over a bridge should be dealt with in the same way as a street repairable by a local authority.

In forwarding these Orders, I am again to thank the County Council and the Committee for the aid which they have given in the matter.—I am, Sir, your obedient servant, R. GIFFEN.

The Clerk to the London County Council,
Spring-gardens."

The Chairman of the Highways Committee said there were still several points in the Orders requiring amendment, and further conference with the Board of Trade would be necessary.

PARLIAMENTARY INTELLIGENCE.

The Select Committee on the Metropolitan Electric Lighting Schemes.

TUESDAY, JULY 16.

The Select Committee of the House of Commons appointed to consider and report upon the various Bills for confirming Provisional Orders granted by the Board of Trade for supplying electric light to districts within the metropolitan area met for the first time on Tuesday, Sir George Trevelyan in the chair, the other members of the Committee being Mr. Story-Maskelyne, Mr. Arthur Duncombe, and Sir Henry Roscoe.

Mr. PEMBER, Q.C., said that he appeared with Mr. Moulton, Q.C., and Mr. Lloyd, on behalf of the London Electric Supply Corporation in support of a Provisional Order issued by the Board of Trade conceding to the Company the right to supply electric light to the parishes of St. George (Hanover-square), St. James (Westminster), St. James and St. John (Clerkenwell), St. Mary (Newington), St. Saviour (Southwark), St. Olave (Southwark), Rotherhithe, Bermondsey, and Greenwich, and parts of the parishes of Chelsea, St. Martin-in-the-Fields, and St. Margaret and St. John the Evangelist (Westmister). The learned counsel observed that the preamble of the Bill was opposed only by the united parishes of St. Margaret and St. John, Westminster, but there were other petitions in regard to clauses. Probably the better course of procedure would be for the Committee to decide one way or the other upon the preamble and then to consider the question of clauses, the decision of the Committee upon which in the case of the first Provisional Order would probably govern the other cases.

Mr. SAUNDERS, Q.C., representing the Westminster Electric Supply Corporation, who were the promoters of the second Provisional Order contained in the Bill, concurred in Mr. Pember's suggestion.

Mr. FREEMAN, who appeared for the London County Council, remarked that his clients had no desire to throw out the preamble if they could secure the insertion of clauses to protect their interests. He thought it would be convenient that the various Bills should be considered practically together, although the points to be raised differed somewhat in the various cases.

Mr. POPE, Q.C., on behalf of the Gas Light and Coke Company, said the Committee would understand of course that his clients did not like the electric light, but at the same time they were not disposed to contest the preamble of the Bill. All they wanted was certain protecting clauses.

Mr. PEMBER, Q.C., then proceeded to further explain the Provisional Order granted by the Board of Trade to the London Electric Supply Corporation and to give details concerning the financial status of the Company. He described at considerable length the system which the London Electric Supply Corporation proposed to employ, and entered into the reasons which had induced his clients to set up a generating station at such a distance from the centres of supply. He concluded by saying that the Company feared no competition and asked no favours.

Mr. STORY-MASKELYNE asked why the promoters applied for the right of supplying only a part of the parishes of St. Margaret and St. John, Westminster?

Mr. PEMBER explained that for the present the Board of Trade had conceded the right of supply in a part of the united parishes to another company. The London Electric Supply Corporation asked for the right in respect only of so much of the united parishes as lay to the north of (but including) Westminster Bridge, Bridge-street, St. Margaret, Parliament-square, Broad Sanctuary, and Victoria-street. The opposition of the Vestry of St. Margaret and St. John to this Bill seemed to be based upon no intelligible principle. They simply placed their back to the wall and, without giving any reason, simply said, "We won't have the electric light."

Mr. POPE, Q.C.: They don't say so, and they don't think so. They simply object to this particular Order.

Mr. PEMBER observed that the Vestry professed to want further time for consideration, and they suggested that the alternating system to be adopted by the promoters would not work satisfactorily. He was quite prepared to go into that question if the Committee wished it, but that would involve a very long inquiry. The point upon which the Vestry seemed most to rely was that under the Act of 1888 a limited power of veto was given to the local authority. It was laid down in that Act that the Board of Trade should not grant any Provisional Order authorising the supply of electricity except with the consent of the local authority, or unless, in cases where that consent was refused, the Board, having regard to all the circumstances of the case, was of opinion that the consent should be dispensed with. In that event the Board was bound to make a report setting forth the grounds of its decision, and that had now been done. To keep the promoters out of the parish of St. Margaret and St. John would be to deny them access to the regions beyond and make it impossible for them to reach their customers. He could not believe that Parliament, in giving local authorities a right of veto, intended it to be applicable in the metropolis. In mapping out London for the general purposes of electric supply such a power of veto would be obviously absurd, although it might operate beneficially where the district to be served, as in Birmingham, was all under one local authority. The parish that was opposing this Order must, so to speak, pay the penalty of its geographical position. London could best be supplied with electricity by large and powerful companies working over large areas and possessing ample capital. That was the deliberate opinion of the Board of Trade, and in mapping out London on that principle they could not attend to the whims and caprices of every local authority. He respectfully submitted that as the Board of Trade was satisfied that the objections of the local authority ought to be dispensed with, the Committee had no jurisdiction in the matter.

Mr. POPE, Q.C., on behalf of the opposing Vestry, urged that the Board of Trade had not complied with the Act of Parliament, inasmuch as they

Digitized by Google

had not given any grounds for dispensing with the consent of the local authority. The Act required them to state their reasons, and they had not done so. All the Board said upon the subject was that the Vestry had been so wanting in vigour in its opposition to the Bill that they had come to the conclusion that after all it would consent. He did not wish to raise any lengthy debate as to the electrical system to be adopted by the promoters, but he maintained that the Vestry was justified in asking that there should be a delay of at least another year before they should be asked to submit to the domination of a Company which, however wealthy and well able to carry out its work, might be experimentally unsound.

Mr. PEMBER having been heard in reply,

The CHAIRMAN said the Committee were clearly of opinion that they had power to go into the objections raised by the local authority, notwithstanding the decision of the Board of Trade to dispense with the local authority's consent. The special report of the Board of Trade as to their reasons for dispensing with the consent did not give the Committee all the information they desired. As to the method of supply proposed to be adopted by the promoters, the Committee did not wish to go behind Major Marindin's report.

Mr. MOULTON, Q.C., suggested that a witness should be called from the office of the Board of Trade, but Mr. Pope objected on the ground that the Board could not supplement by oral explanations a report required to be made by Act of Parliament.

After some discussion,

The CHAIRMAN said the Committee felt they must decide the case upon its merits. Without wishing to criticise the special report of the Board of Trade he must repeat that it did not give the Committee all the information they desired. On the other hand, it would not be proper to call the Board of Trade officials as witnesses unless they could be subjected to cross-examination.

In answer to Mr. Story-Maskelyne, Mr. POPE said he did not propose to call any witnesses. He would be content to leave the matter as it stood in Major Marindin's report.

The EARL OF CRAWFORD, examined by Mr. Moulton, said he was Chairman of the London Electric Supply Corporation, and had given great attention to the whole subject of the proposed working of the company, scientifically and financially. He believed the company to be sufficiently rich and powerful to carry out satisfactorily the work allotted to it by this Provisional Order. He believed the electric light would be much used in the district covered by the Provisional Order. Probably as many as 30,000 lights would be required in Victoria-street alone. The principal residents there were well-to-do occupants of flats who lived more luxuriously there than they would do in houses of their own.

Cross-examined by Mr. POPE, witness admitted that it would not be unreasonable for a local authority to wish to retain in its own hands the right of supplying the electric light if it showed any *bonâ fide* disposition to do it.

In answer to Mr. Freeman, LORD CRAWFORD said it was proposed to carry the mains over Westminster Bridge. He believed that that could be easily done without danger or inconvenience. It was true that arrangements might be made with the South-Eastern Railway Company to carry the mains over Charing Cross Bridge, but the promoters did not wish to place it in the hands of any company to be able to cut them off at any moment. He had considered the possibility of carrying the mains under the river, but there were practical and legal difficulties in the way. The promoters did not wish to be in a worse position than the gas and water companies, whose mains were carried over the bridges.

Mr. FREEMAN remarked that the gas and water companies acquired their powers before the bridges became public property.

The room was cleared, and on the readmission of the public,

The CHAIRMAN announced that the Committee found the preamble of the Bill proved, subject to the insertion of clauses providing for an audit of the company's finances, and imposing certain conditions as to the user of Westminster Bridge and the sufficient supply of electrical energy.

The Committee then adjourned.

Wednesday, July 17.

The Committee resumed their inquiry on Wednesday morning, Sir George Trevelyan in the chair.

Mr. POPE, Q.C., on behalf of the vestry of the united parishes of St. Margaret and St. John, Westminster, said that after the decision announced by the Committee on the previous day, he would reserve any further opposition, so that he might not be prejudiced when the Bill reached the other House.

Mr. SAUNDERS, Q.C., who appeared for the Westminster Electric Supply Corporation, hoped he might now take it that the preamble of the Bill was proved. He would call a witness if the Committee thought it necessary for him to do so. The Order which had been granted in favour of his clients was, except in regard to capital and works, in terms identical with that granted to the London Electric Supply Corporation. His clients were a modest company, created simply for the purpose of dealing with two districts in the west part of London, viz., the parish of St. George (Hanover-square) and a part of the united parishes of St. Margaret and St. John (Westminster). Over a certain portion of this area the London Electric Supply Corporation had also the right of supply. With the exception of the houses in Victoria-street, the district was a poor one. It was proposed to adopt the low tension continuous-current system. As the local authority had no objection to the Order asked for by the Westminster Electric Supply Corporation, he appealed with confidence to the Committee to confirm it. The Company had already expended a certain amount of capital, was thoroughly *bonâ fide*, and had its works in the actual neighbourhood that it proposed to supply, and it was not under the necessity of asking for permission to carry its mains over any of the Thames bridges.

The CHAIRMAN said the Committee were satisfied with the general statement they had heard, and Mr. Saunders need not call witnesses. The Provisional Order would be confirmed.

Provisional Order Bill No. 3 was next considered.

Mr. C. BAGGALLAY said he appeared in support of the Order granted by the Board of Trade to the House-to-House Electric Light Supply Company for portions of the parish of St. Mary Abbott, Kensington.

The CHAIRMAN said the Committee approved the Order.

Mr. SAUNDERS, Q.C., appeared to support the Provisional Order granted by the Board of Trade to the Kensington and Knightsbridge Electric Lighting Supply Company, which was to look after portions of the two parishes named. There was no opposition. They were already at work, supplying the Kensington Town Hall and other buildings. There was an increasing demand, and the company only awaited the Parliamentary confirmation of this Order to enable them to increase their generating stations, the land for which they had already acquired.

In reply to Sir H. Roscoe, the learned counsel said that his clients proposed to use the continuous current system.

The CHAIRMAN: We confirm the Provisional Order.

The next case was that of the Notting Hill Electric Lighting Company, whose Order was confirmed.

Mr. SYDNEY MORSE supported the Provisional Order of the Chelsea Electricity Supply Company having reference to a part of the parish of South Kensington (St. Mary Abbot). There was no opposition, and the Order was confirmed, as was also an Order in favour of the Electricity Supply Corporation for the district of St. Martin's-in-the-Fields.

On the application of Mr. CRIPPS the Committee also confirmed Provisional Orders conceding to the Metropolitan Electric Supply Company the right of providing electric light in the districts of St. Giles, Holborn, Strand, and St. Marylebone. An Order in favour of the same company in respect of Lambeth, Streatham, and Clapham was withdrawn, in consequence of the local authorities not having given their assent. Mr. Cripps stated, in answer to the Committee, that the Metropolitan Electric Supply Company would have a supply station on the south side of Waterloo Bridge, and that they would work generally on the alternating-current system, though they would have one station conducted on the direct-current system.

The Committee, having approved the preambles of all the Bills, proceeded to consider the clauses, and it was agreed to insert provisions as to the audit of accounts of the various companies. It was further suggested, at the instance of the London County Council (represented by Mr. Freeman) to make provision against the amalgamation of electric lighting companies, or the transfer of their Parliamentary powers, without the consent of the local authorities concerned.

Mr. GRAY, who appeared for the Board of Trade, said that with regard to one of the proposed amendments by the London County Council, it seemed to the Board of Trade to go directly in the teeth of the 11th section of the principal Act, which made the Board of Trade to be the authority which must consent to any consignment of powers.

Mr. FREEMAN denied that the proposed clause would override the principal Act, and said that he could not see that the Board of Trade had any ground for interfering when the promoters, the Committee, and the County Council had agreed to the clause.

The CHAIRMAN asked if the difficulty would not be removed by putting the clause in the confirming Bill.

Mr. GRAY said it was unusual for a Bill which had the effect of a special Act to use words overriding the principal Act.

The CHAIRMAN said that the Committee did not think they would be discharging themselves of their responsibility without seeing that any amalgamation of these important companies should be done in the full light of day and with the sanction of Parliament. The question was how this was to be done.

In answering, Mr. FREEMAN submitted that the clause would in no way interfere with the Board of Trade's power to grant new licenses. An amalgamation could not be made by a new license.

Mr. C. BAGGALLAY hoped that the clause would be framed so that the companies could associate for certain purposes, and thus economise their power.

Mr. FREEMAN said that they desired to guard against association as well as amalgamation.

The CHAIRMAN said that from Sir E. May's "Parliamentary Practice" it would appear that amending of the preamble was the proper method to carry out the intentions of the Committee.

Mr. FREEMAN said that the London Company had agreed to the clause, with the following addition, to which he assented:—"But this provision shall not prevent any temporary arrangement under which the Undertakers may obtain from any other Undertakers the supply of electricity with the consent of the Board of Trade and the County Council."

Mr. WALLACE said he must, on behalf of the Companies he represented, object to this amendment, which would be of no use to the London County Council.

Mr. GRAY objected to the amendment on the ground that it overrode a clause in the Provisional Order preventing one company supplying energy beyond its own legalised area of supply.

Mr. BAGGALLAY repeated his objection to the words "associate with," as being too wide. The company he represented would not object to any association requiring the consent of the Board of Trade, or to any amalgamation requiring the consent of Parliament.

Mr. CRIPPS said that the companies could not carry on their business with this non-association clause in.

Mr. MOULTON pointed out that it would prevent his company carrying out one of the purposes for which it was formed, viz., the supply of electrical energy to other companies.

Digitized by Google

Mr. GRAY thought it was undesirable that there should be two authorities to give the consent for this temporary association.

The CHAIRMAN said that the Committee would require only the consent of the Board of Trade; and the words requiring the consent of the London County Council were accordingly struck out.

A clause was agreed to providing that 28 days' notice should be given by the Undertakers before commencing to lay mains in any street.

Mr. FREEMAN observed that the 28 days' was a compromise, although his clients (the London County Council) thought it too short a time.

Mr. MOULTON said: As to the arbitration in the case of carrying the supply over bridges, he felt it absolutely necessary that competent persons should be appointed as arbitrators, as there was a good deal of responsibility in arranging electrically how the supply was to be carried over, and a person not competent might not be able fully to appreciate the difficulties of the task he had to deal with. In case there should be a serious difficulty it was most important to the public that the matter should be decided upon by some impartial person appointed as the Committee might think fit.

Mr. FREEMAN then proceeded with Clause 13, and submitted that his clients having better knowledge of all the bridges, the crossing of the bridges should be subject to their direction.

The Committee having deliberated, the CHAIRMAN said the Committee were perfectly willing to give every possible guarantee to the County Council as to the method in which the bridges should be crossed. They wished to give the greatest latitude to the County Council in the matter of the arbitrator, but in the last resort the arbitrator must be appointed either by the Board of Trade or by someone else.

Mr. FREEMAN accepted that at once, and would endeavour to carry it out; but if, when the County Council came hereafter to consider it so important that the arbitration should not be put upon them, they reserved their rights.

The CHAIRMAN suggested that they should adjourn the gas clauses, not knowing how long they would take.

Mr. POPE thought the gas clauses might be disposed of to-morrow, and explained the mode of procedure he proposed to adopt with regard to them.

The Committee then adjourned till Thursday.

THURSDAY, July 18.

The Select Committee for the consideration of these Bills held its third meeting yesterday (Thursday).

Mr. MOULTON, Q.C., said the only remaining opposition to clauses was from the Gas Light and Coke Company, and he proposed now to bring the clauses of the Bill before the Committee.

Mr. POPE, Q.C., objected to this on the ground that the promoters were adhering to the clauses in the Provisional Order; he was entitled to bring forward his clauses, which would give him the right of reply.

The CHAIRMAN ruled that Mr. Pope should bring forward his clauses.

Mr. POPE said the discussion would practically settle the Model clauses for all such Bills in future, and for all gas companies. His clients did not desire to put forward clauses merely to obstruct the competition in lighting which the Bill would set up, but only wished that wrong and injustice should not be done to those already in possession of the field. The position of the gas company was that they were entitled to precisely the same protection for their pipes as any other owners of property were entitled to. If the electric company happened to damage the pipes of the gas company the latter were entitled to bring an action at law against the former unless the work they were doing was protected by Act of Parliament, and the Provisional Order had practically the same effect as an Act of Parliament in that respect. His clients wanted to secure that no damage should be done to the Gas Company's works, and that the construction of the electric works should be such as not to make it difficult for and impede the Gas Company in getting at their works for the purpose of perfecting their supply. He then proceeded to place the clauses before the Committee.

Mr. J. O. PHILLIPS, secretary and manager of the Gas Light and Coke Company, examined by Mr. BIDDER, gave details of the affairs and works of the company, in the course of which he said they had laid 1,850 miles of mains in their district of supply. It was very necessary that they should be protection clauses, as any damage to their pipes might cause a stoppage of the gas supply which might lead to serious consequences, especially as the signal lights of the Metropolitan Railway were lighted by their gas. His company desired proper notice of the works of the Electric Company, so that one of their officers might be present to see that no damage was done to the pipes; they wanted no favour. He suggested that the electric mains should be laid not less than five feet from the gas mains, and that the Gas Company should have a fortnight's notice of any works being done by the Electric Company.

Mr. C. WOODALL, civil engineer, called by Mr. BIDDER, said there must be a certain inclination in gas pipes, and so it was of importance that the gas company should make any alteration in them which was necessary. The pipes required frequent examination and renewal, and it was important that nothing should be placed over them which would prevent such work. Protection was alike necessary when gas pipes were interfered with, or works undertaken near them. He thought an absolute distance of 5ft. from the gas mains would be excessive, and that a limitation was undesirable. It would be better to give notice to the companies interested. In answer to Mr. Moulton, he said he thought a week's notice was fair for all new works, but there were special cases when less should be required.

Mr. MOULTON said his clients would not object to that.

WITNESS said he thought the gas companies should superintend the carrying out of the works as well as the digging of the trenches.

Mr. MOULTON again said his clients would not object to that.

WITNESS, in reply to Mr. Moulton, said he should like to see clause 17, relating to new works, agree more with clause 16, relating to repairs. He wanted the gas company to have an alternative to do the works, other than electric works, and to let the Electric Company have a similar right in works other than gas works.

It was explained to the Committee that the Court, which would have jurisdiction under Section 17, was that of a metropolitan police magistrate.

In further cross-examination, WITNESS said he thought it was better to give the gas company an alternative to do the work, instead of arbitration, which would delay the work.

Mr. G. C. TREWBY, engineer to the Gaslight and Coke Company, also gave evidence as to the necessity of notice, and

The CHAIRMAN said the Committee quite recognised the seriousness of full notice, and of the gas and electric companies working together in laying down the pipes.

WITNESS proceeding, said that 48 hours' notice of new works was insufficient for them to ascertain what was necessary by way of precaution. So far as he knew no damage had been done to their mains by the Knightsbridge culvert, but as the ground had been filled in they really did not know how the work was done.

Mr. MOULTON, after some discussion, said his clients were ready to amend clause 17 so as to give seven days' notice instead of 48 hours' notice, to give a right of superintendence of the execution of the work mentioned in the clause, and to give the Gas Company the option of themselves performing the work exclusive of the electrical part, if the London County Council did not exercise the prior option which they had under the Bill.

Mr. BIDDER said he accepted the compromise, except as to notice, which he still held should be fourteen days.

Some discussion then took place, in the course of which Mr. MOULTON agreed that no part of the gas mains should be used as an electric circuit or as a pediment for the electric companies works, and that the method of insulation should be decided by an arbitrator to be appointed by the Board of Trade.

Mr. BIDDER accepted those points, and clauses were to be drawn accordingly.

Mr. MOULTON promised to bring up a clause providing for arbitration in case of dispute, under section 17.

The Committee then adjourned, it being understood that the clauses should be brought up at this day's (Friday's) sitting.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The thirty-fourth half-yearly ordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. George Draper) read the notice calling the meeting and the minutes of the last half-yearly meeting, which were confirmed by the present meeting.

The report of the Directors was taken as read.

The CHAIRMAN said that the report was very full and very instructive, and he hoped it would be thought a very satisfactory one by the shareholders. The revenue account for the half-year ended March, 1889, showed a total amount for messages of £352,791, being an increase over the corresponding half of 1888 of £28,647. About two-thirds of this increase arose from their South African traffic and from the political disturbances which had been going on at Zanzibar. The South African traffic had been largely developed by the mining enterprises, and they were sanguine that even in ordinary times the traffic would be a satisfactory and increasing one. Holding these views, they had, in concert with the Eastern and South African Company, organised a complete alternative system of telegraphy to the Cape *vid* the West Coast. This growth of traffic had enabled the South African Company (the greater part of whose capital was held by the Eastern Company) to pay a largely increased bonus. The shares of the Eastern and South African Company were all but entirely held by the Eastern Company. The revenue account showed that the Eastern Company had received as dividend £79,650, against £31,200 in the corresponding half-year. The £79,650, however, included an exceptionally large bonus from the South African Company. He was pleased to say that their Egyptian traffic, which had been steadily declining for some years, showed an increase in the past six months as compared with 1888. One class of traffic, namely, the Indian, showed a substantial decrease. This falling off, which amounted in the past half-year to £5,500, was engaging their serious attention. Their Black Sea dividend was the same as last time, but their investment in the Direct Spanish Company was £184 less. To sum up, their gross revenue from all sources for the half-year was £435,932, or an increase of £76,226 over that of the same half of 1888. The total working expenses for the half year had been £92,448, showing an increase of £5,314. In giving the details of the increases and decreases in the expenses, he stated that the increase in the expenses at the stations had been owing in a great measure to the addition to their foreign staff, consequent upon the opening of the triplicate cable from Porthcurnow to Lisbon, Gibraltar, and Malta, and the extension to Zante, and to the opening of a new station at Cadiz, they having put that place in telegraphic communication with Villa Real and Gibraltar. It had also been necessary to augment their staff at other stations. As compared with March, 1888, the total increase in the number of their staff at the stations was 41. To meet the requirements of the traffic they had found it

Digitized by Google

necessary to add to the accommodation of several of their stations, more particularly in London and at their training school at Porthcurnow and also at Carcavellos, Malta, Alexandria, Suez, Syra, &c. The repairs to the cables in the half-year had cost £48,665, or £10,253 more. The expenses of five ships were included this half-year, against four in the same period of 1888, and also the cost of 203 knots of cable used in repairs and renewals, the greater portion of which was used in the extensive repairs to their No. 1 Aden-Bombay cable. The total increase in their revenue had enabled them to meet the additional expenses incurred during the half-year, and to pay an extra ½ per cent. bonus on the ordinary shares, including the 20,000 additional shares issued to enable them to take up a like number of ordinary shares of the Eastern and South African Company. They had placed £118,000 to the reserve fund, against £75,000 last year. The reserve fund, with interest received on investments during the half-year, the premium on the issue of new shares, the profit on the sale of Direct Spanish Company's Debentures, and the contribution from revenue account (£118,000) for the year ended 31st March last, now amounted to just over half a million. They had spent on their system out of their reserve and revenue accounts £782,000, and he thought that showed they were in a most satisfactory position. Their object was to keep down the capital as much as possible, and at the same time maintain such an efficient system as would command the support of the public and lead to a still further development of the telegraphic system. At the last meeting he told them that they were engaged in a very great and important work, the laying and completing of a system of submarine telegraphy round Africa by the West Coast. They had just completed that work, which was probably the most important work yet done in submarine telegraphy. But the surrounding of Africa by submarine cables could not have been done except by organisation. In early days they showed that unless the West Coast cables were extended to the Cape the two or three existing companies could do no good whatever. They, however, felt that the traffic to the Cape was such that it had become necessary for them either to duplicate their system on the East Coast or lay an alternative line by the West Coast. After due consideration they adopted the latter course, and he might say that England, Portugal, France, Spain, the Cape of Good Hope, and Natal were all more or less directly interested in these cables, and had given their support to the great work which had been finished. It was a remarkable fact that while the Eastern Company during the last fifteen years, owing to the growth of business and extension of their system, had increased the volume of traffic 370 per cent. their income had not increased more than 100 per cent. The fact was that they had some very clever people to deal with, the merchants having brought their coding systems to such a high state of perfection. Further reductions in the rates were, however, sometimes talked about, but they could not reduce the rates unless they could increase their traffic and income. He thought that the distribution they were declaring that day must be generally accepted as a fair and satisfactory one. Notwithstanding what he would call the very encouraging prospects and the solid position of their Company, they had a great deal of work before them yet. Some of their cables were getting old, and they wanted to increase their capital as little as possible. They looked to a very large increase in their Australian traffic, in connection with which they would probably have to make reductions in the tariff, but they would take care, if anything of the same nature were suggested with the Indian traffic, to see their way very clearly before they made any alteration. One of their cables, from Aden to Bombay, required very special attention, and if the traffic increased as they expected, and as it was doing, to Australia and other parts, they would require to put down another cable, not only between Aden and Bombay, but from Marseilles to Egypt, to give them perfect security and safety. While carrying out the very great work which the share holders would themselves see had to be done, the Directors would endeavour to maintain the income of the Company, and while adding to the value of their property and not increasing the capital they would try and make the same satisfactory dividend as they now had the pleasure of proposing. He concluded by moving a resolution adopting the report and accounts, declaring a dividend on the preference shares at the rate of 6 per cent. per annum, less income-tax, paying a dividend of 2s. 6d. a share, with a bonus of 3s. a share, tax free, on the ordinary shares, making, with previous payments, 6½ per cent. on the ordinary shares for the year ended March 31st, 1889.

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the motion, which, after some discussion, was adopted.

On the motion of Mr. JOHN NEWTON, seconded by Dr. WALLER, a vote of thanks to the Chairman and Directors was passed, and the proceedings then terminated.

A full report will appear in our next issue.

Telegraph Construction and Maintenance Company (Limited).

A half-yearly general meeting of this Company was held on Tuesday, at the offices, 38, Old Broad-street, Mr. P. Rawson presiding.

The MANAGING DIRECTOR having read the notice calling the meeting,

The CHAIRMAN expressed regret at the absence of Sir Daniel Gooch, the Chairman of the Company, and said: This meeting, as you are aware, is nothing more than a formal one. We have no resolutions to propose, nor any report to lay before you.* The warrants for the interim dividend will be posted this afternoon. I have very little to say to you. I will just lay before you a synopsis of what we have done during the half-year which has just passed. We have done a fair share of cable work during the half-year, especially as regards the wire-covering and other general business of the Company. Our ships have been engaged in triplicating a portion of the Eastern Extension Company's system between Java and Western Australia, and in laying a line between the Cape and the Portuguese settlement of Mossamedes, on the West Coast of Africa. We have also effected some cable repairs on the west side of the Atlantic, and the steamship "Calabria" continues on the charter she was engaged in at the time of the last annua report.

The proceedings then terminated.

* The interim dividend was 12s. per share, as announced in *The Electrician* of July 5.

London Electric Supply Corporation (Limited).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel on the 15th inst., under the presidency of the Earl of Crawford.

The MANAGER and SECRETARY (Mr. Charles B. Waller) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen—We have met here to-day in order to carry out the promise which your Board made to you at the time of the last meeting. They then presented their annual report to you, and told you they were about to lay the accounts of the past year before you. The business that we have to-day is to lay those accounts before you, with a copy of which you have been supplied. Before going into any question of these accounts I wish to inform the shareholders officially now that their Board has been materially strengthened by the addition thereto of Mr. J. S. Forbes, who has come upon the directorate as Vice-Chairman and Chairman of the Finance Committee. Your Board, in requesting Mr. Forbes to take this position among them, thought they were doing their very best for the interests of the shareholders in carrying out this arrangement. Mr. Forbes has been good enough to go very carefully into all matters relating to finance, and he will explain to you the whole of these accounts which are laid before you. I may say that the form in which the accounts have been presented and produced now is mainly upon the lines laid down by the Board of Trade for the accounts which are to be presented by all the electrical companies in future. They are based somewhat on the lines of the accounts produced annually and laid before Parliament by gas companies, and I think that anyone who knows anything about figures will be able to see from them how we stand as far as our financial position is concerned. Without going further into them, I will move—

"*That the accounts now submitted be and are hereby approved.*"

And I will ask Mr. Forbes to go into the question of accounts, and also to answer any question that any shareholder may desire to know.

Mr. J. S. FORBES, in seconding the motion, in the course of his remarks, said: It is very desirable at starting that the proprietors should be thoroughly versed in the manner in which the accounts have been stated. They ought to have been submitted for the year ended December 31, but there were reasons which prevented that from being done, and the Directors thought it would be desirable, as some considerable time has elapsed since then, that you should be, so to speak, posted to date. They, therefore, upon the first sheet of the accounts set forth the statement of capital at the various periods—the statement of share and loan capital at the 31st December, 1888, and the 31st March, 1889. Since December, as you were made aware at the special meeting, there has been an alteration in the method of raising the capital of the Company, and that is shown in the statement to March. The capital of the Company is £1,000,000, divided into 200,000 ordinary shares of £5 each, authorised by the Memorandum of Association and the Articles, and £536,300 of that amount has been called up. Then, in accordance with the resolution of the annual meeting held in December last, £250,000 of preference capital was authorised, in 50,000 shares of £5 each, of which £1 a share has been called up. The amount of capital called up was therefore at the 31st March £586,300. There remains unissued £445,000 of ordinary share capital, £200,000 of preference capital, and £18,700 of the ordinary capital, being the £1 a share that is unpaid on the 18,700 shares on which £4 each has been called up. Having all this capital still to call up is a material fact, in this sense—that the authorities in dealing with the applications of electric light companies for licenses for supplying certain districts require strong assurances that they are not mere bogus companies who intend to hawk about the rights they may acquire and dispose of them to someone else. They will, therefore, only entrust such licenses to companies having a substantial backbone, as your Company has. The way in which the money called up has been disposed of is also shown. Up to December 31 you see that £374,617 was expended, and as the works are going on further money has been spent from day to day. During the quarter ended March £18,340 has been added to the expenditure, so that the outlay has been £392,957 up to that date, and the balance to the credit of the capital account was then £193,342. One has to consider the application of this large sum of money, and how far the experience of the working justifies that expenditure and justifies the hope which is entertained very strongly on the Directors' side of the table that the money has been very wisely spent in a sound enterprise, and one which is likely to be very soon, if not immediately profitable. The revenue account to December 31 has been made out in great detail in order to supply the fullest information as to the expenditure under the headings of generation of electricity, distribution of electricity, rent, rates and taxes, management, legal expenses, &c. You have two generating stations, the Grosvenor Gallery station, which is the active generator at the present moment, and you have the great work which is being carried out at Deptford, which in course of time will supersede the Grosvenor Gallery station. These expenses represent, so to speak, the cost of production of your article, which is made in one place and distributed, by a total different process, to a great number of other

Digitized by Google

places. On the opposite side of the revenue account you see the kernel of the nut—the result of this large expenditure. I assume that no shareholder would suppose that a business of this sort, so very novel and having to contend with such great difficulties, would in the first period of its existence at once burst out into a position of great prosperity. What we have to consider is whether the initiatory period, which must of necessity involve great expenditure on the one hand, and comparatively small revenue on the other, is of such a character as to induce in the minds of business men the belief that the undertaking is sound. Having gone through the revenue account to December 31st, he said: It therefore seems that during these fifteen months of what may be called the inception of the business there was really a slight loss—the income was absorbed by the working expenses. In that period, however, the business was of a broken kind; there were few customers compared with the expenses of generation, distribution, and the fixed charges, and probably a great deal of the current that was generated was not utilised at all. I think I may say, in general terms, that if all the current that was produced in this period could have been distributed, sold, and paid for, the result, instead of being a small balance against you, would have been a sensible balance in your favour. In order to test whether the result to December was a fair start, we have made a revenue account for the first three months of this year, to March 31st—a period during which the thing was still in a transition state. Customers and the public are slow to follow in these cases. A great many wait to see what will turn up. They do not believe that the price charged is the lowest, or that the supply offered is the most efficient, and they go on waiting from month to month—and perhaps they act wisely. They will, however, come in when they know that they are dealing with a company properly constituted, with legal responsibilities, and with the power to perform them. Now, turning to the revenue account for the three months to March 31, you see that there is a change for the better. Instead of there being a loss of £382, as there was on the working for the fifteen months up to December, there is a profit of £548. That is not a large profit upon the capital that is spent. It is only useful in indicating that we have, as it is called, "turned the corner;" and the same observations I have made as to the generation and distribution of electricity hold as good in connection with the three months I am now dealing with as they did in the previous fifteen months—that is to say, if all the electricity generated had been sold and paid for the result shown would be very different. What is going on is this:—Knowledge and experience and scientific investigation are bringing the thing into harmony, and from three months to three months you will see much more of an equilibrium than you do at the present time. What the Board are waiting for is the completion of the great works at Deptford. Those works are of course very bold and very costly, but they will, when finished, do at a comparatively small relative charge what smaller works could not have done. They will put you in a position to meet an enormous increased demand upon you at a cost which could not be achieved by any multiplication of business upon a much smaller scale. The principle is at once to create an enormous amount of electricity, and by conducting it to various parts of London to reduce the cost of production and the fixed charges of production to the lowest possible figure *pro rata* to the amount of current generated, distributed and sold. I think I have said enough upon the question of the revenue accounts. They are really only useful at this stage of the Company's existence as, first of all, stating intelligently the outgoing and incoming element, and in showing also that although the fifteen months' working to December was not profitable to look upon, the working for the three months to March, under the influence of more experience, reduced cost, and more customers, has presented rather a better aspect; and I need not tell you that if that £548 for the quarter goes on rapidly increasing, as it probably will—as every member of the Board thinks it will—when the Directors meet you in future the result will be a great deal more satisfactory. The balance sheet is brought down to the 31st March, but I do not know that I need make any remarks on it, though if any shareholder desires any information upon it I shall be glad to supply it. I now second the resolution.

Mr. KISCH inquired the meaning of the item of debenture discount, £3,000 in the general balance-sheet on December 31, how it was that that item had risen to £30,000 by March 31, and how such an item at all was consistent with the statement on the first page of the accounts, that the loan capital on March 31 was *nil?*

Mr. FORBES replied that the item of loans has disappeared entirely by the 31st March. At the beginning, the Company, under the sanction of a general meeting, raised money by debentures—they were authorised to raise £180,000 at 4 per cent., the price of issue being £120 of debentures for £100 of cash. It was thought later on that it was unwise to have any mortgage debt in such a Company, and the debenture holders, in the exercise of the option given to them, took ordinary shares. He thought that this change was a very wise one in the interests of the Company. In further reply, Mr. Forbes stated that the expenditure at the Grosvenor Gallery since the 31st December, up to March, had been only £30.

The CHAIRMAN, in answer to another question, stated that the sum of £211,000 represented the price of the undertaking taken over by the present Company. It included the whole of the mains laid up to that time—about 60 miles laid all over London, the machinery then in existence, and the whole of the freehold property at Deptford.

The motion was then put in the usual way, and was carried.

The CHAIRMAN: That concludes the work that we have practically to do to-day, but I think I should say a few words on the present state of your property, and on what has occurred since I had the pleasure of addressing you on the 21st December last. At that time I told the shareholders that we were doing all we possibly could with respect to obtaining the Parliamentary powers which were necessary for us to do our work underground instead of working overhead. Overhead cables, no doubt, are a very useful means of going about London or any place, but they entail considerable labour and risk to ourselves. When I say risk I do not mean risk of danger, but risk of interference owing to the impossibility of our obtaining any permanency for those cables, because they are always at the mercy of a single individual, who says, "Take the pole off my house," and if you have to do that, you have to cut off the whole circuit of which that pole is a small portion. On the 21st December we had prepared (and I showed you at that time) the proposal we were then placing before the Board of Trade, laying out the form in which we desired to have statutory powers. I then showed you a large map coloured, with a great stroke of red on it, showing that we were proposing to take powers over a very large portion of the metropolis. After that time passed we had many interviews with the local authorities, and we had to modify, in many cases, the ideas we had formed, in order to meet their views. We had interviews with local authorities, vestries, and all the persons interested in what we were proposing to do—that is, to break up the streets. Having arranged as nearly as possible with them, we went to the Board of Trade at a certain date, and presented our proposed order. The action of the Board of Trade then began, and we had many interviews, but we could not persuade that body to adopt our views altogether, and they determined at the instance of the local authorities and others to hold what is called a local inquiry. That local inquiry was commenced on the 3rd of April. It held a continuous sitting for a period of eighteen days. During that time Major Marindin, who was appointed Inspector to report on those Provisional Orders to the Board of Trade, had before him all the objections that could have been raised to the Orders. He had before him all the different areas which the various companies desired to have. He considered these matters, and in the course of time he made a report to the Board of Trade stating what in his view ought to be carried out. That report has been presented to Parliament and can be obtained by anyone for 5½d. It contains the report of Major Marindin *in extenso*. It contains also certain correspondence between the Board of Trade and the County Council, and at the end of it, it contains a Model Order which the Board of Trade drew up—the model form of a Provisional Order in which they practically lay down that every one working in the Metropolis is to be put exactly on the same lines. With respect to what Major Marindin gave out in his report I have no objection to take to it in so far as it affects our interests. On the contrary, I am perfectly well satisfied with what he offered us, and I think that the proprietors of this great business will have every reason also to be satisfied with it. We have been given powers over 13 local authorities in London. Beginning in Deptford, we have the Greenwich parish, Rotherhithe, Bermondsey, St. Saviours, St. Olaves, a portion of Lambeth, Chelsea, St. Margarets, and St. John's, Westminster; St. George's, Hanover-square, St. James's, Westminster, and a portion of St. Martin's-in-the-Fields. That was the recommendation that Major Marindin made. He also said if we had any means of obtaining access into Clerkenwell that that parish should be added to our Orders. We were fortunate in being able to make arrangements with the railway companies giving us access to that district, and Clerkenwell has accordingly been added to that Order. Since the time that that recommendation was made, the parish of Newington, in South London, appealed to the Board of Trade, saying that they would be deprived of the light unless they came to us, so the Board of Trade have added Newington. We have, therefore, now a very large area. The main principle of Major Marindin's report was, that where it is possible two companies should be put into the same area. That I had the honour to state to you was entirely our view—that we were opposed to monopoly *per se*, that we were perfectly willing, where we had powers, that other companies should have powers also, relying upon our being able to do the work in a proper and business-like manner. The area where we have competition at present is St. George's, Hanover-square. We have there against us, or I should say more properly alongside of us, the Westminster Company. Similarly that Company has power over St. Margaret's, Westminster. In Chelsea we have the Chelsea Company alongside of us. In the portion of St. Martin's that we have, we have alongside of us the Metropolitan Company, and again that Company extends its powers over a small portion of Lambeth parish, over which we have taken jurisdiction. The parts lying to the east of Lambeth on the south side of the river are at present served by us alone. No company has yet been promoted for working that district, though, no doubt, in future some other companies will come and seek to have power with us. We shall not be against them, and so far as we can, we shall be ready to offer them facilities. There was one important recommendation of Major Marindin's report to this effect: In our generating station at Deptford he thought that it would be desirable to split up the building into two portions longitudinally. He put in his report that the building must be subdivided in such manner, or else that we should have a further generating station at another point. I was able to show him that the dividing up of the engine room as he suggested was not feasible, and also that the dividing it up as he suggested would not really carry out the objects honestly which he wished to see; that is, that every large engine should be insulated practically—have a wall or something like that between it and its neighbour. I also showed that the advantage to the public was one with an advantage to the shareholders in saying that if anything is to be done to our generating station the money had far better be placed in another place—in another generating station in another quarter of London, also advantageously situated as regards the getting of coal, labour, and so forth. The Board of Trade were willing to agree to that, and they will, therefore, call upon us in a short time to commence the erection of another station in another place. Instead of putting straight away now four large machines at Deptford, we are to put two at Deptford and two at the other place, and shall have a far better reserve of power, so that in case of a breakdown at either place we should have the other station at which to carry on the work. I think the actual difference of expenditure that will be caused to the proprietors will not be very great, but merely the expense of obtaining the land and buildings.

Digitized by Google

The machines will be put into the two different buildings instead of one. Later on, when we have to add to our plant, one machine will go to Deptford and one to the other place as a reserve. As to what has occurred since I last addressed you, on the 21st December, you will remember that early in April last year we commenced working upon our Deptford land. That land was then perfectly rugged. Hardly anything was done on it except the pulling down of some brick sheds. Since then we have put up a very large building indeed, and are in a very fair way of commencing active operations there. We have put up a building consisting of boiler houses, engine houses, &c., covering an area of 40,000 square feet. The cubic capacity of the buildings runs up to something like 3,000,000 cubic feet. We have erected boilers to the extent of 12,000 horse-power. The boilers have been tested up to 300lb., and are again being tested at a higher rate, and have been under steam. We have erected and run two engines of 1,500 horse-power each, which can be started and worked in a very short time now. Possibly many of you may remember that a short time ago we had an unfortunate accident throught a steam pipe breaking. It was practically through no fault of the Board or of any one as it was owing to the inherent qualities of copper when under pressure. When soldered it is impossible to know how these copper pipes will be acted upon by steam. However, it is the best means known of working. That accident, which I regret to say resulted in the death of an unfortunate labourer, caused us to take down the steam connections from the engines and re-test them up to a much higher pressure than previously, and these connections are being again made. I trust in a few days that the engines will be actually working. The dynamos to be worked by these 1,500 horse-power engines are in a very far advanced state of completion. We expect in a short time to have these two machines working, each machine being able to do more than the Grosvenor Station is able to do at present. We have made arrangements that the very moment we start at Deptford we shall be able to relieve the work at the Grosvenor Station to the extent of something like 15,000 or 16,000 lights from Deptford. The Grosvenor Station, I think, as noted just now, will be done away with in the course of time. That is the case, but we do not wish to stop the working at that station until we can conveniently dispense with it. I suppose, therefore, it will go on for four or five months longer. We shall certainly be able to work our Deptford Station before the powers we seek to obtain will be afforded to us. That is to say when Parliament is good enough to confirm the Order made by the Board of Trade we have certain formalities to go through with those Orders which are laid upon us before we can do anything to the streets. We cannot in future erect overhead cables, but must put them underground, and I here may say that the depreciation underground is nothing to what it is overhead. Among the formalities that we have to go through is one that notice of a month has to be given to the local authority, County Council, Postmaster-General, gas and water companies, and everyone else before we are allowed to break the ground If we got our Order this month you might assume that we could begin in September, but that is not the case, for all the local authorities put in the Order a clause where they state that no part of the month of August should be counted as a month. We shall only, therefore, be able to give one month's notice on the 1st September, and we shall begin to break ground on the 1st October. I have no hesitation in saying that before that time we shall have everything ready at Deptford for supplying the current and of relieving the Grosvenor Station of some 16,000 lights. We have been able to make arrangements that will enable us to do that without incurring any additional expense. The first two large engines that I alluded to last time and which were authorised by the meeting formally—the 10,000 horse-power machines—are well advanced. The main difficulty of this operation was to get what is known as the crank shafts of the dynamos. These crank shafts have been cast in Scotland. They are of steel, and the casting was over 75 tons in weight. The shafts when finished will weigh over 60 tons, and I think the magnitude of our undertaking will be understood when I tell you that this was the largest casting ever made in Scotland. We have two of these machines in hand, and as a wise precaution we thought it well to order three of these shafts, so that they will be ready should anything happen to either of the other two, or for putting in a third machine when it is necessary for us to do so. The engines for driving these two large dynamos are ready for delivery when we are ready to receive them. The wharf which runs along the river frontage for 195 feet is entirely finished. We have got a large steam crane upon it capable of making a lift of 50 tons all in order. We have made a railway from the river front right through the property to the street frontage of our premises, and the permanent way is thoroughly satisfactory in all respects. We have two travelling cranes working on it, each lifting and moving about ten tons, and in one engine-room we have a travelling crane capable of working 25 tons, and in the other a travelling crane capable of working 50 tons. The other important part of the work finished since we last met is the main-making machinery. That has got to a state of efficiency, which leaves very little to be desired. We are able to receive the copper in tubes, make the insulation, put on the outside tube, and insulate again at very considerable speed—and without requiring any very great-skilled labour—an important point. The work is almost automatic. Each of these main-making machines is capable of turning out about a-half mile of main a day, so that you see we are well within our capabilities of working. In fact, I think the mains will be put out faster than we can open the ground to receive them. I do not know anything else to mention that would interest you or that I have omitted to tell you. I think altogether you have every reason to be satisfied with your property, and I am sure that anything that can be done by the Directors to enhance its value will be done as it always has been done. I think that concludes the business of the meeting.

On the motion of Sir PHILIP MAGNUS, seconded by Mr. R. I. WALLER, a vote of thanks was passed to the Chairman and Directors for the care which they have taken in carrying out the works of the Company and promoting its welfare.

The CHAIRMAN briefly returned thanks, and the proceedings terminated.

The Direct United States Cable Company (Limited).

The following is the report of the directors for the six months ended 30th June last, to be presented at the twenty-fourth ordinary general meeting of the Company, to be held at Winchester House, 50, Old Broad-street, E.C., on Friday, the 26th inst., at two p.m. :—

1. The usual statements of account for the half-year ended 30th June, 1889, accompany this report, and together with the half-year's accounts to 31st December last, presented at the ordinary general meeting on the 25th January last, show the financial result of the twelfth year's working of the Company.

2. The half-year's revenue (still subject to revision) including income-tax refunded, and after deducting out-payments, amounted to £39,662. 8s. 5d. against £17.507. 17s. 2d. (after similar deductions) for the corresponding period of 1888, being a difference of £22,118. 11s. 3d. in favour of the half-year under review resulting from the current tariff.

3. The working and other expenses for the same period, including income-tax, but exclusive of cost of repairs of cable, amounted to £16,626. 3s. 9d., leaving a balance of £22,950. 4s. 8d. as the net profit of the half-year, making with £11,641. 13s. 3d. brought forward from the previous half-year a total of £34,591. 17s. 11d. For the corresponding half-year of 1888 the working expenses and other payments amounted to £15,276. 11s. 10d.

4. Three quarterly interim dividends of 2s. per share for the quarter ended 30th September last, and of 3s. 6d. each per share for the quarters ended 31st December and 31st March last, amounting to £27,319. 10s. 0d. have been declared and paid during the financial year, and a final payment of 3s. 6d. per share is now proposed, making, with the three interim dividends, 3½ per cent. for the year, being a total distribution of £37,943. 15s. 0d. The balance of £2,719. 2s. 11d. on the revenue account is proposed to be carried forward.

5. The 1s. tariff continues, and the receipts have been largely increased, but a fairly remunerative revenue has not yet been attained. The traffic, however, is exhibiting signs of expansion.

6. An interruption of the main cable occurred on the 19th April last, on the "Green Bank," and was repaired on the 19th May. The cable was found to have been broken by a vessel's anchor. The cost of the repair, £4,474. 1s. 11d., has been charged to the reserve-fund account as usual. On the other hand, the sum of £7,315. 19s. 2d., being the interest and dividends received and profits realised on the sale of securities has been added thereto. The Directors do not on this occasion propose to further increase the reserve fund.

7. The appeal of the Cie Française du Télégraphe de Paris à New York referred to in the last report, was heard on the 12th, 14th and 19th March last, when the Council of the Prefecture of the Seine declared in effect that they had no right to enter into the Joint purse Agreements. An appeal to the Council of State is now pending.

8. Pursuant to the provisions of the Articles of Association, two of the Directors, viz., Admiral of the Fleet, the Hon. Sir Henry Keppel, G.C.B., D.C.L., and Admiral R. C. Mayne, C.B., M.P., retire by rotation, and being eligible offer themselves for re-election.

9. Mr. John G. Griffiths and Mr. John Sawyer, the Auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

The Edison and Swan United Electric Light Company (Limited).

The following is the sixth annual report of the Directors of this Company for the year ending 30th June last, to be presented to the general meeting of shareholders to be held at the Cannon-street Hotel, London, E.C., on Tuesday, July 30th, at twelve o'clock.

The sale of lamps and fittings has progressed in a satisfactory manner during the year, and has resulted in a credit balance of £47,729. 5s. 9d.; to this must be added the sum of £25,123 9s. 7d., the balance of account for the year ending 30th June, 1883, making a total of £72,852. 15s. 4d., out of which the Directors have appropriated the sum of £28,815. 14s. 2d. to meet losses realised on finally disposing of sundry installations taken over at the date of the amalgamation, and have, under Clause 89 of the Articles of Association, created a reserve of £4,595. 10s. 10d., and they recommend the appropriation for dividend, in accordance with Clause 87 of the Articles of Association, of 7 per cent. upon the amount paid up on the A shares, in respect of the year ended 30th June, 1889, and of 3 per cent. further on account of the arrears of preferential dividend on the A shares in respect of the year ended 30th June, 1884.

The Supply Companies are establishing central stations in London and the Provinces, which must lead to a considerable extension of the business of the Company.

The appeal of the Company from the decision of Mr. Justice Kay was heard before Lords Justices Cotton, Lindley, and Bowen, who reversed Mr. Justice Kay's judgment, and decided that Mr. Edison's patent, 10th November, 1879, was valid.

The Brush Company gave notice of their intention of appealing to the House of Lords, but a settlement has been arrived at by which the case will not be carried to the House of Lords. The Brush Company give up manufacturing incandescent lamps, and they pay the taxed costs of the action.

Viscount Anson and Mr. Ernest Villiers retire from the Board and offer themselves for re-election as Directors.

Messrs. Welton, Jones and Co. (late Messrs. Quilter, Welton and Co.), the auditors, also retire, and offer themselves for re-election.

The Anglo-American Brush Electric Light Corporation (Limited).

The following is the report of the Directors of this Company to the shareholders, to be presented to the extraordinary general meeting to be held at the Cannon-street Hotel, on the 22nd inst., at 2 o'clock :—

The Directors announce that the Mortgage Debentures which were offered for subscription in April last have all been allotted, the applications for the same having been in excess of the amount to be allotted. As a result of obtaining this additional capital, the directors have been enabled to give effect to the policy indicated in former reports, of extending the capacity of the Corporation for carrying on its manufacturing operations ; and a provisional contract has been made to acquire the business and properties of the engineering establishment known as the Falcon Works, at Loughborough, in Leicestershire, upon the terms mentioned below.

The directors have also entered into a provisional agreement with the Australasian Electric Light, Power and Storage Company for the transfer to the Corporation of its business as a going concern. The Australasian Company, which is one of the companies formed in 1881-1882 to work the Brush and Lane-Fox patents, has also acquired by its amalgamation with the Edison Indian and Colonial Company the patent rights of Edison in India, Australasia and South Africa. The policy of re-acquiring the rights held by the subsidiary companies has already met with the full approval of the shareholders, and the terms of the proposed arrangement, which in the opinion of the Directors are fair and equitable to both companies, are mentioned below.

The Memorandum of Association of the Corporation, which was drawn up many years ago, before the present requirements of an electrical manufacturing and contracting company were realised, has been found to be inadequate. It is therefore necessary for this, as well as for a variety of minor reasons, to extend and amend the Memorandum of Association, and as this can be legally accomplished only by means of a re-constitution of the Corporation the Directors have given the whole position their very careful consideration, and now submit for the approval of the shareholders the scheme of reconstruction mentioned below.

The Directors take this opportunity of announcing the settlement of the litigation with the Edison-Swan United Electric Light Company (Limited) in regard to Incandescence Lamp Patents. Under the arrangement come to, the Edison-Swan Company accept a license to use the Lane-Fox and other Incandescence Lamp Patents held by the Corporation, and they pay the Corporation a royalty upon the basis of the number of lamps made, but subject to a maximum payment per annum. The Corporation, on the other hand, give up the manufacture of incandescence lamps, and agree to buy from the Edison-Swan Company on the most favoured terms to dealers, until the expiry of the Edison patent. The Edison-Swan Company waive all claim to damages, and it will be remembered that in regard to the Cheeseborough patent, the decision of Mr. Justice Kay was against the Corporation and no appeal was entered, but the Corporation agree to pay the Edison-Swan Company's taxed costs. The arrangement, which applies only to the United Kingdom, fully protects the Corporation's customers, who will not be subjected to any inconvenience or expense.

The only other litigation in which the Corporation is engaged is that relating to Compound Winding of Dynamos. It will be remembered that in the case against the Orient Steamship Company, which was tried in England in December last, the Brush patent for this process was upheld ; on the other hand, the action brought by Messrs. King, Brown and Co., in Scotland, for the reduction of the patent has been decided in favour of the plaintiffs. This decision is now being appealed against, but the issue will not in any way affect the manufacturing business of the Corporation.

With regard to the general business of the Corporation, the Directors are glad to be able to report very satisfactory progress. It is not practicable to specify in detail the important contracts at present on hand and in view, but it will be interesting to the shareholders to know that the orders booked during the first six months of this year equal in amount the total volume of last year's business, and when it is remembered that the past year showed a very considerable advance upon the business done in previous years, it will be admitted that the present position of the Corporation is very satisfactory, and justifies sanguine expectations in regard to the future.

The Amalgamation with the Falcon Company.—The Falcon Company was established in 1883 to take over the works and business of the Hughes Engineering Company. The capital is £60,000, divided into 50,000 Preference Shares of £1 each, and 10,000 Ordinary Shares of £1 each. The Company has, since its formation, carried on successfully the business of building locomotive and other engines, as well as tramway and other cars. For the four years ending June, 1886, the full dividend of 7 per cent. per annum was paid upon the Preference Shares ; in the following year a dividend of 2 per cent. was paid, and the dividend paid in 1888 on the Preference Shares was 5 per cent. The property consists of freehold land covering an area of over seven acres, and several buildings well adapted to the purposes of iron and brass founding, engine and car making, stores, offices, dwellings, &c., and, on the whole, the property is well adapted for the Corporation's heavy electrical work. The price to be paid for the whole of the business as a going concern is £55,000, in fully-paid shares of the new Company, and £1,000, payable half in shares and half in cash, to cover expenses incidental to the liquidation of the Falcon Company.

The Directors of the Corporation consider the arrangement very advantageous for the following, among other, reasons :—

(*a.*) Additional manufacturing works are absolutely necessary for carrying on the business of the Corporation ; (*b.*) the works of the Falcon Company are suitable for the purposes of the business ; (*c.*) the situation of the works is very convenient in respect of economy of manufacture and of conveyance of goods and materials ; (*d.*) the purchase price is to be in shares, involving no cash expenditure, except such as may be necessary for extensions and the amount mentioned above for expenses ; (*e.*) the business of the Falcon Company is carried on at a profit, and as it is proposed to continue the same, the capital expended on the purchase will not be unproductive during the period of transition necessary for the adaptation of the works to the new requirements ; (*f.*) there will be no loss of time in the acquisition of the property, and this, in view of the urgent demand for a much larger output than the Corporation is at present able to deal with, is an advantage of very great importance, and one that could not be as effectually secured by any other available means.

Amalgamation with Australasian Company.—The Australasian Company was formed in 1882 to work the Brush and Lane-Fox patents in the Australasian Colonies. The Company, as already stated, subsequently amalgamated with the Edison Indian and Colonial Electric Company, and secured the patent rights of Edison in India, Australasia and South Africa. It has also secured the sole agency under the Swan Lamp patents and other rights. The Company therefore occupies an exceptionally strong position in regard to some of the principal patents which control the more important branches of the electrical industry. Last year the Company carried out, by means of apparatus supplied by the Corporation, the important contract for lighting the Melbourne Centennial Exhibition, and altogether the Company has done important work in organising the business in the Colonies, but it has not, so far, been able to work at a profit, the volume of business having during the past years of depression been but small. The prospects now, however, have materially improved. Under the agreement with the Australasian Company hitherto in force the Corporation has been practically precluded from doing business in Australasia, except through the medium of the Australasian Company, and in the opinion of the Boards of both Companies the Corporation will, by reason of its manufacturing facilities and greater experience in the field of electrical work, be in a better position for developing the business in the Colonies than the Australasian Company. The present capital of the Company is £202,386, divided into shares of a variety of classes ; but under a scheme of reconstruction, which is now before the shareholders of that Company, it is proposed to consolidate all classes of shares, and to reduce the aggregate capital to £78,065. The price to be paid by the Corporation for the transfer of the business as a going concern is £45,000, payable in fully-paid shares of the Corporation or of the re-constituted Brush Company, as mentioned below, and £1,000 payable half in shares and half in cash to cover the expenses of winding up.

Scheme of Reconstruction.—It is proposed to transfer all the assets and liabilities of the Anglo-American Brush Electric Light Corporation to a new Company to be registered under the title of the Brush Electrical Engineering Company (Limited), with extended Memorandum and Articles of Association. The present subscribed capital of the Corporation is 52,314 shares of £5 each = £261,570. (Of these 25,803 shares are £5 fully paid up and 25,511 are £5 each with £4 per share called up.) The capital of the new Company is to be £750,000, divided as follows :—£300,000 in 150,000 Six per cent. Preference Shares of £2 each, £450,000 in 150,000 Ordinary Shares of £3 each.

The proposal is, that the shareholders of the Corporation shall receive in respect of each £5 fully paid share held by them one Preference Share of £2 and one Ordinary Share of £3 in the new Company ; that the Falcon Company shall receive £55,500 in 11,500 Preference Shares of £2 each and 11,100 Ordinary Shares of £3 each ; and that the Australasian Company shall receive £45,509, in 9,100 Preference Shares of £2 each and 9,100 Ordinary Shares of £3 each.

The arrangement will involve the voluntary liquidation of the Anglo-American Brush Electric Light Corporation, and in view of the desirability of removing the distinction at present existing between the partly-paid and the fully-paid shares, by which the market value of the shares is affected, it is proposed that the liquidators should call up the £1 per share remaining unpaid on 25,511 shares.

It will be necessary to obtain the sanction of the debenture holders to the scheme, but as it is proposed to issue debentures of the new Company of equal amount to, and on the same terms as, the present issue, the debenture holders will in view of their security being materially increased by the accession of the assets of the Falcon and Australasian Companies have every reason for acceding to the arrangement.

Digitized by Google

The share and debenture capital account of the new Company will stand thus :—

Nominal share capital	£750,000
Mortgage debentures	75,000

The Directors are advised that the subdivision of the capital in the way proposed will tend to appreciably improve its market value, and the numerous precedents for this course afforded by the large railway and other companies strongly support this view. It is obvious that as a result of this proposed subdivision of the capital the shareholders will have much greater certainty of receiving satisfactory dividends upon at least a portion of their holdings than if the profits of the business had to be distributed over the whole of the capital alike.

In conclusion, the Directors are of opinion that the present is a very favourable opportunity for carrying out a scheme of this nature, which has been under their consideration for some time past, but which, owing to the late unfavourable condition of the industry, and to the want of adequate working capital necessary for effecting the enlargement of the works, has not been practicable before. After a long period of depression, the business has now entered upon a new and more encouraging phase, and by taking energetic steps to cope with the increasing demand for electrical work of every kind, the Company will, it is confidently believed, forthwith place itself in a dividend-paying position. The character and the amount of the work now carried on by the Corporation and the prospects of future business are such that the Directors see no reason why the new Company should not, from the date of its registration, earn sufficient profits to admit of regular dividends being paid from the outset. The Board are of the opinion that the opportunity of the reconstruction should be taken to strengthen the Directorate. They propose to offer seats at the Board to one Director of the Falcon Company and one Director of the Australasian Company, and they are in consultation with some of the leading shareholders as to the advisability of appointing one or more additional Directors. The Directors further refer to the notice convening a special meeting of the shareholders and the resolutions set out, and they strongly recommend these resolutions for adoption in the full conviction that the course suggested will be found to be in every respect beneficial to the shareholders.

The folowing are the resolutions referred to :—

Resolution No. 1.—"*That the Provisional Agreement entered into between the Corporation and the Australasian Electric Light Power and Storage Company (Limited), dated the 12th day of July, 1889, and submitted to the meeting be, and the same is hereby sanctioned, adopted, and confirmed, and that the Directors be authorised to carry the same into effect with or without modifications.*"

Resolution No. 2.—"*That in accordance with the terms of the Agreement mentioned in the above resolution, the Directors shall, if necessary, issue to the Liquidators of the Australasian Electric Light Power and Storage Company (Limited), or to such persons and in such manner as the Liquidators shall in writing direct, fully paid £5 shares in the capital of the Corporation not exceeding 9,100 in the aggregate.*"

Resolution No. 3.—"*That it is desirable to reconstruct the Anglo-American Brush Electric Light Corporation (Limited), and that with a view thereto the Corporation be wound up voluntarily, and that J. B. Braithwaite, Junr., and E. Garcke, be, and they are hereby, appointed Liquidators for the purposes of such winding up.*"

Resolution No. 4.—"*That the said Liquidators be, and they are hereby, authorised to consent if required to the registration of a new Company to be named 'The Brush Electrical Engineering Company (Limited),' with a Memorandum and Articles of Association which have already been prepared with the approval of the Directors of the Corporation, but which are to be subject to such alterations and modifications, if any, as may be found expedient.*"

Resolution No. 5.—"*That the Draft Agreement submitted to this Meeting and initialled by the Chairman for the transfer of the business and property of this Corporation to the new Company shall be and the same is hereby approved, and that pursuant to Section 161 of the Companies Act, 1862, the Liquidators shall be, and they are hereby, authorised to enter into an Agreement with such new Company (when incorporated) in the terms of the said draft, and generally to carry the same into effect with such (if any) modifications as the Liquidators may find expedient.*"

Should resolutions 3, 4, and 5 be passed either with or without modification by the required majority, they will be submitted for confirmation as special resolutions to an extraordinary meeting which will be subsequently convened.

In reference to the amalgamation referred to above, the following is an abstract of a circular sent to the shareholders of the

Australasian Electric Light, Power and Storage Company (Limited).

"I am instructed to inform you that the Directors have entered into negotiations with the Anglo-American Brush Electric Light Corporation, with a view to amalgamation with that Company. . . . .

Your Directors have, therefore, felt justified, in the interests of all classes of the shareholders, in abandoning the scheme for reduction of capital and the issue of preference shares proposed in the circular of 23rd January last, and have entered into an agreement, subject, of course, to the approval of the shareholders, by which the new Brush Company will take over the entire business of the Australasian Company, including all liabilities and assets, as hereinafter explained.

The consideration to be paid by the new Company is a sum of £45,000 in preference and ordinary shares, which will be available for distribution among the shareholders, inasmuch as the Brush Company, in addition thereto, pays expenses of liquidation. As it is not possible to speak with absolute accuracy of the position and liabilities at the present moment in Australia, it has been necessary to provide for the possibility of a reduction of this amount in the event of unforeseen liabilities appearing, or in the event of any of the patents having lapsed ; but the Directors have taken all practical precautions on these points, and do not anticipate any material modification under this head.

The shares of the Anglo-American Company at present are of the denomination of £5 each, some fully paid and others £4 paid, but the unpaid portion on these latter will now be called up for the purpose of equalisation. These £5 shares are quoted 4¼ ¾, and it is now proposed, in the amalgamation, to make two classes of shares, the present £5 share being represented by one preference share of £2 entitled to 6 per cent., and one ordinary share of £3 entitled to the residue of all the profits.

As in the case of the Anglo-American Company, it will be necessary that the 10s. per share now remaining due upon a certain number of the shares of the Australasian Company should be called up for the purpose of equalisation.

According to the Articles of Association of the Australasian Company the sum of £45,000 would be divisible in the following proportions between the original ordinary and the ordinary (Edison) shares, viz. : — The original ordinary £5 shares will be entitled when fully paid up to £39,815, equal to about £1. 10s. 3d. per share. And the ordinary (Edison) £1 shares (already fully paid), being only entitled to rank for 50 per cent. of their face value in any distribution of assets, will be entitled to £5,185, equal to about 3s. 1d. per £1 share.

The Directors anticipate that the shareholders will reap considerable advantage from the much better quotation and freer market which it may be expected the shares of the Brush Electrical Engineering Company will enjoy than is possible, in the circumstances, with the shares of the Australasian Company. . . . .

By order of the Board,
J. H. DUNCAN, Secretary."

"Dear Sir,—An extraordinary general meeting of the shareholders in this Company will be held at the offices of the Company, No. 39, Coleman-street, in the City of London, on Tuesday, the 23rd inst., at 3:30 o'clock, for the purpose of considering a proposed sale of the property and assets of the Company to the Anglo-American Brush Electric Light Corporation, (Limited), and in the event of the proposed sale being approved by the shareholders, the following extraordinary resolutions will be proposed to be passed :—

Resolution No. 1.—'*It is hereby resolved to adopt, ratify and confirm the Agreement, dated the 12th day of July*, 1889, *and made between the Australasian Electric Light, Power and Storage Company, of the one part, and The Anglo-American Brush Electric Light Corporation (Limited), of the other part; and the Directors are hereby authorised and requested to do all things that may be necessary for the purpose of giving effect to the said Agreement, and carrying out the provisions thereof, either with or without modification.*'

Resolution No. 2.—'*That the Company be wound up voluntarily, and that Mr. John Henry Hill Duncan, of 39, Coleman-street, in the City of London, Chartered Accountant, and Mr. Emile Garcke, of Belvedere-road, Lambeth, be and they are hereby appointed joint Liquidators of the Company upon the terms specified in the above agreement of the 12th day of July instant, and with instructions to carry the said agreement into effect, with or without modifications approved by the Directors.*'"

Exeter Electric Light Company.

The first meeting of this Company will be held next week. The Directors report that numerous obstacles had been raised which greatly retarded the introduction of the electric light into the city, but they had persevered in their efforts, and they have now succeeded in overcoming difficulties which at one time appeared almost unsurmountable. A central depôt has been purchased in New North-road, close to the railway. After referring to the accounts, the Directors state that the demand for electric lighting in Exeter has more than realised their expectations. Already a large number of arc lamps and about 1,000 incandescent lamps have been applied for. Contracts have been entered into for lighting several public buildings and places of worship, and some of the most enterprising citizens, including the proprietor of two of the principal hotels, have decided to light their premises with the electric light. The Taunton Electric Light Company (Limited), which was formed upon a similar basis to the Exeter Company, and which employs the same system, paid 5 per cent. the first year and 6 per cent. the second year, besides carrying forward a considerable sum for reserve and depreciation, and this year it is expected that a dividend of not less than 7 per cent. will be earned. The Directors see no reason to doubt that results equally satisfactory will be achieved in Exeter. The share capital already subscribed, including shares agreed to be taken, amounts to £7,000.

NEW COMPANIES REGISTERED.

THE ECUADOR TELEPHONE COMPANY (LIMITED).—Registered by Slaughter and May, 18, Austinfriars, E.C., with a capital of £100,000 in £5 shares. Object—to carry into effect an agreement made between W. A. Pittman and the Ecuador Telephone Company (Limited), to acquire any lines of telegraphs, telephones, or other means of communication in Ecuador. There shall not be less than three nor more than seven directors. Qualification, £1,000 stock. Remuneration to be determined in general meeting.

THE WESTINGHOUSE ELECTRIC COMPANY (LIMITED).—Registered by Norton, Rose, Norton and Co., with a capital of £600,000 in £10 shares. Object, to acquire certain patents, goodwill, business, inventions, machinery and property of the American company, known as the Westinghouse Electric Company; to carry on the business of makers and suppliers of and dealers in electricity, electric power and light, to create, produce, store, accumulate, supply, hire, and lease electricity, electric power or other similar agency for any purpose; to acquire all land, estates, factories, personal property, rights, and privileges requisite or convenient for the purposes of the company whether from the Westinghouse Electric Company in America or elsewhere. The first subscribers are:—Sir H. W. Tyler, M.P., Pymms-park, Edmonton; F. Parg, Foley House, Portland-place; J. D. Gibbs, 18, Warwick-street, Regent-street; C. C. Macrae, 20, Cheyne-walk, Chelsea; W. D'Oyley, 24, Westbourne-terrace, W.; H. T. Norton, 57½, Old Broad-street; H. R. Laing, 3, Drapers'-gardens, E.C. There shall not be less than three, nor more than 12 directors. Qualification, 100 shares. The first are F. Parg, Sir H. Tyler, J. D. Gibbs, G. Westinghouse, jun., and J. Humbard, the last two not joining the board till after completion of purchase. Remuneration, £2,000 per annum, divisible as they agree.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—At a meeting of the Board of Directors of this Company held on Monday last, it was resolved to declare an interim dividend for the quarter ended 30th June last, of 15s. per cent. on the Ordinary Stock, and £1. 10s. per cent. on the Preferred Stock, less income tax, payable on the 1st August to the stockholders registered on the books of the Company on the 10th July, 1889.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended July 12, 1889, amounted to £4,150.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—At a meeting of the board of directors of this Company, held on Friday, it was resolved to recommend a final dividend of 3s. 6d. per share, free of income tax, payable on and after the 27th inst., making, with the interim dividends already paid, 3⅛ per cent. for the year ending 30th June last, carrying forward a balance of £2,719 2s. 11d. The register of transfers will be closed from the 12th to the 26th July, both days inclusive.

THE DIRECT SPANISH TELEGRAPH COMPANY.—This company will remove to their new station, No. 74, Gracechurch-street, during the night of Friday, the 19th inst. The whole building, which is fitted up in the most complete manner for the purpose, has been occupied by the telegraph department of the company. The station works direct with Bilbao (875 miles) and with Madrid by translators at Bilbao (1,190 miles). It has also communication by pneumatic tube with the General Post Office in St. Martin's-le Grand. In order to adapt the building to the requirements of the company extensive alterations have been made, the architect being Mr. A. E. Thompson, of Leadenhall-buildings, and the contractor Mr. A. Porter, of Tottenham. The comfort of the staff and the sanitary arrangements have been particularly attended to, the whole of the drains having been arranged in the most improved manner.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—This company announce that the coupon on the Six per Cent. Debentures, due August 1, will be paid on and after that date at the Consolidated Bank, Theadneedle-street, E.C.

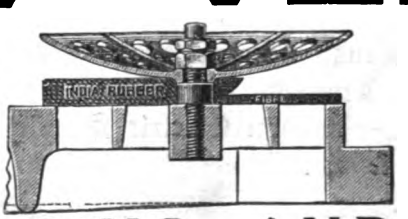
GLOBE TELEGRAPH AND TRUST COMPANY.—This company announces a balance dividend of 4s. per share, making a total of 4⅛ per cent. for the year ending the 18th inst., carrying forward £2,043.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 12, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,793.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this company for the half-month ended July 15, 1889, amounted to £2,519, as compared with £2,544 for the corresponding period last year. The March receipts, estimated at £7,394, realised £7,37[illegible].

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 584.—Vol. XXIII. FRIDAY, JULY 26, 1889. Price Fourpence.

NOTES.

We publish this week a second article from the pen of Dr. S. Doubrava upon the distribution of high-tension continuous currents with transformation by means of condensers. Notwithstanding the well-recognised advantages of a practicable system of continuous-current transformation, no one, so far as we are aware, has hitherto thought it worth while seriously to to investigate the inherent capability of the condenser, the difficulties in the way of affecting the necessary reversals being at first sight insuperable. Yet this difficulty has been overcome by Dr. Doubrava in the simplest and most effective way. It is simply a question of causing the commutator to synchronise with the natural period of the condenser when charged under constant E.M.F. A moment's consideration will show that if a disconnection is effected *at the moment when the condenser is fully charged* there is no difference of potential at the points of separation, and consequently no possibility of sparking. The whole system, which is very ingeniously worked out, depends, therefore, upon the speed of the commutator synchronising with the period of charge and dischgare of the condenser. At present Dr. Doubrava proposes to have only one commutator, which is placed at the generating station, or, if preferred, at a sub-distributing station. This arrangement avoids the difficulties of synchronising so long as all the condensers are of the same capacity; but, on the other hand, as we shall then have an intermittent current in the mains or sub-mains, the special advantages of the continuous current are abandoned. At present we fear that Dr. Doubrava's system is more interesting and ingenious than it is practica.

According to the original programme of the promoters of the Paris Exhibition it was proposed to institute a series of exhaustive tests upon electrical apparatus similar to those carried out in previous years, at Paris in 1881, at the Crystal Palace, at Vienna, Munich, Philadelphia, and Antwerp. This intention has, however, been allowed to fall through, and the building which was originally intended to enshrine a magnificent laboratory of electrical engineering was at an early stage assigned to meaner uses. Whether or not this should form a subject for serious lamentation is a question upon which there may easily be more opinions than one. In the earlier days of the industry accurate and reliable data of the performance of dynamos, motors, lamps, and accumulators, were urgently required, and we are deeply indebted to the promoters of the Exhibitions which have just been enumerated for furnishing the opportunity to obtain such statistics, whilst we are still more indebted to those by whom the elaborate tests were so ably carried out. It must, nevertheless, be recognised that such experiments as it is possible to execute upon these occasions, however skilfully they may be designed and conscientiously executed, cannot possibly take into consideration every circumstance which determines the relative commercial value of the apparatus experimented upon. For our own part we are strongly of opinion that *as a general rule* it would be fairer and more useful—as well as less invidious—to institute a *pass* rather than a *competitive* examination in these cases. Let the Committee draw up certain conditions (the degree of stringency of which would of course be in each case a subject for the most careful consideration), and let them then content themselves with issuing certificates to all firms whose apparatus is found to fulfil the required conditions without assuming the responsibility of affirming that A's apparatus is superior to either B's or C's. An effective examination of this kind could be carried out in less time and with infinitely greater certainty than the present system will admit, whilst we have little doubt that the results would give far greater satisfaction to exhibitors in general, and would infallibly lead to a large increase in their numbers. As an additional advantage it might easily be arranged that upon the application of any individual exhibitor the exact figures recording the performance of his apparatus should be issued under the certificate of the Committee.

We do not know, nor are we much concerned to inquire, whether the suggestion made in the above paragraph is or is not original; but we do venture strongly to recommend it to the serious consideration of all who are responsible for the conduct of Exhibitions, at least where electrical apparatus is concerned. Especially do we urge it upon the consideration of the Executive Committees of the forthcoming Exhibition at Birmingham and that to be held next year in Edinburgh. The principle may not be applicable in all cases, but as regards at least the most important appliances of electrical engineering, its successful enforcement would, we imagine, present no very serious difficulty.

At Paris, as we have intimated above, it is not at present intended to carry out any electrical tests whatever.

Digitized by Google

Medals and Certificates are to be awarded to the exhibitors at the discretion of the Committee, and will therefore be taken for just what they may be supposed to be worth. It is, however, worthy of note that without exception all the more prominent firms of electrical engineers of French nationality have already placed themselves out of the running, and are declared "*hors concours*" by reason of their having one or more representatives upon the Executive Committee. The spoils will, therefore, be divided betwixt America, Switzerland, and Belgium, with perchance a scanty tribute to this country, though we take it that the chief of the small array of English exhibitors are likewise *hors concours*.

We understand that the Metropolitan Telephone Service has now been handed over from the United to the National Telephone Company, and the officers of the latter company are engaged in making a thorough investigation into the existing state of affairs. That they will discover magnificent opportunities for effecting improvements in the service we do not doubt in the least, and we shall be greatly disappointed if the highly successful results attained in Manchester, Glasgow and Dundee are not eventually reproduced in London in spite of the confessedly greater difficulties of the undertaking. Meanwhile, in common fairness to the technical staff of the late United Company, it must be remembered that their efforts have from the first been hampered by a policy which has now been overturned; indeed, no fair opportunity of dealing with the problem has ever been afforded them.

After devoting four sittings last week to the consideration of the Metropolitan Electric Lighting schemes, the Parliamentary Select Committee concluded its labours on Friday, confirming the several Provisional Orders and agreeing on a report to the House. Stringent rules have been introduced with regard to the Companies' accounts, which are to be audited by the Board of Trade, and also a distinct prohibition of amalgamation or association except with the sanction of Parliament. Reciprocal arrangements were agreed to between the Gas Companies and the Water Companies on the one hand, and the Electric Companies on the other, with reference to the digging of trenches, so as to mutually safeguard their property underground. These provisions are not likely to be disturbed in Parliament, where the Bills are down for third reading this week.

The sectarian squabble over the Technical Education Bill has resulted, as we last week feared it would, in its virtual withdrawal, the Government confessing their inability to meet the wishes of the two conflicting parties by any compromise that would be agreeable to both. Mr. W. H. Smith has promised a measure this session dealing with "higher" technical education—meaning apparently that, for the present, elementary schools are not to be assisted at all in that direction. The new Bill was read a first time on Wednesday.

It was, we suppose, inevitable that as soon as the electrical purification of sewage had been shown by Mr. Webster to be commercially feasible it would be discovered that there were several possible ways of purifying sewage by electricity. A discovery of this description has apparently been made by M. Hermite, of electric bleaching fame, whose modification of the Webster process is now being tried on a large scale at Rouen. Where sea-water is available M. Hermite proposes to pump it into an "electrolyser," and after converting it therein into a powerful disinfectant it is to be used in lieu of fresh water to flush the drains and water the roads. The cost of chemicals is, of course, in this method *nil*, though since it involves, if thoroughly carried out, the laying of a duplicate set of mains, the first cost is likely to act as a strong deterrent. In inland towns M. Hermite's process merely consists in passing the town sewage through a battery of "electrolysers" containing common sea salt, from one to five kilogrammes of which, he estimates, will be required per cubic metre of liquid (say, from 70 to 350 grains per gallon), so that on a moderate reckoning the Hermite process must be several times more costly than that of Mr. Webster. When we add that M. Hermite employs anodes of platinum and kathodes of zinc, and in lieu of simply passing the effluent through an inclined shoot, maintains the circulation of the liquid by means of a turbine, it will be evident that the modified process is scarcely an improvement on the original.

The alternator designed by Mr. C. F. Brush and Mr. G. Pfaunkuche for the American Brush Company (of which a further account will be found in the letter of our New York correspondent) may be briefly described as a Mordey armature set in a revolving field of the Siemens' alternate pole type. The machine is designed for 110 alternations, with 2,000 volts terminal pressure. The transformer is chiefly noteworthy from the fact that simplicity of design and construction has been to some extent sacrificed with a view to obtaining high efficiency over a large range of output.

Electric Lighting in Australia.—Steps are being taken both at Newcastle (New South Wales) and Fitzroy (Victoria) to have the streets lighted by electricity.

Blackrod.—An Electric Lighting Company have notified their intention of applying for a Provisional Order to supply electricity in the Blackrod Board's district.

Gloucester.—At the last quarterly meeting of the City Council it was announced that several electric light companies had made proposals for lighting the city by electricity.

Milnrow.—The Lancashire and Cheshire Electric Light Company have given notice of their intention to apply for powers to introduce the electric light into the Milnrow district.

Malvern.—The Birmingham House-to-House Electricity Company have given notice that they intend applying for a Provisional Order to supply electricity in the Malvern district.

The Obock-Perim Cable.—The cable between the Island of Perim and the French colony of Obock has been successfully laid by the Eastern Telegraph Company, and is now working.

Horwich.—The Local Board has received a notice from the Lancashire and Cheshire House-to-House Electricity Company intimating that they intend to apply for a Provisional Order.

Edmonton.—Notice has been served on the Local Board by the House-to-House Electric Light Supply Company of their intention to apply to the Board of Trade for a Provisional Order.

Digitized by Google

The Telegraph in China.—The telegraph line across China from Shanghai and other ports to Momein or Tengyueh, which is about 100 miles from Bhamo, has been completed within the last few weeks.

Stroud.—At a recent meeting of the Stroud Board of Health the Clerk read a communication from the Western House-to-House Electricity Company giving notice that they intended to apply for a Provisional Order.

Melton Mowbray.—At the last meeting of the Melton Mowbray Local Board the Clerk read a letter from the Midland House-to-House Electricity Company, stating that they intended to apply for a Provisional Order.

Maindee.—At a recent meeting of the Christchurch Local Board, a letter was read from the House-to-House Company announcing their intention of applying for a Provisional Order to light the Maindee district by electricity.

Stafford.—The Midland House-to-House Electricity Company have served the Stafford Town Council with notice that they intend to apply for a Provisional Order. The matter was referred to the General Purposes Committee.

Stourbridge.—At the last meeting of the Town Council a notice was read from two electric lighting companies of their intention to apply to the Board of Trade for powers to supply the inhabitants of this town with electric light.

Fareham.—At a public meeting of the ratepayers of Fareham last week it was decided to reject the offer of the Gas Company to sell the gasworks to the town, and to invite tenders for lighting the parish with "gas, oil, or otherwise."

Chiswick.—At a recent meeting of the Chiswick Local Board the Clerk read a notice from the House-to-House Electric Light Supply Company of their intention to apply for a Provisional Order. It was referred to the Works Committee to report.

Moss Side Local Board.—At a meeting of the General Purposes Committee the assent of the Board was given to the proposal of the Manchester House-to-House Electricity Company to supply electricity for public and private purposes within the Board's district.

Gillingham.—At the last meeting of this Board notice was received from the Municipal Electric Light and Power Company of their intention to apply to the Board of Trade for a Provisional Order for power to supply the electric light in the Board's district.

Nuneaton Local Board.—At the last meeting of this Board the Clerk read a communication from the Midland House-to-House Electricity Company, giving notice of their intention to apply for a Provisional Order, and asking the consent of the Board to the application.

Lightning.—There are grounds for believing, says the *Centralblatt*, that the blue lightning flashes are the most powerful, but do not cause fire, whereas those of a reddish colour are less in power but do cause ignition. What the grounds *are* is not stated.

Oldbury.—At a recent meeting of the Oldbury Local Board of Health the Clerk reported that he had received a notice from the Midland House-to-House Electricity Company, intimating their intention to apply for powers to supply electricity within the Oldbury Local Board District.

Twickenham.—Notices of intention to apply for Provisional Orders for Twickenham have been received from the South-Western District of the Thames Valley Electricity Supply Company, the South of England Electricity Company, and the Counties Electricity Supply Corporation.

Clee Local Board.—At the last monthly meeting of this Board a communication was read from the Midland House-to-House Electricity Company, intimating their intention to apply for a Provisional Order to authorise the employment of electricity within the district of Clee-with-Weelsby.

Stonehouse.—At a recent meeting of the Stonehouse Local Board the Clerk read a notice from the Devon and Cornwall Electricity Supply Company, stating that it was their intention to apply for a Provisional Order. The application was granted subject to the plans of the company being in accord with the bye-laws of the Board.

Shrewsbury.—At a recent meeting of the Shrewsbury Town Council a notice was received from the Midland House-to-House Electricity Company to the effect that they intended to apply for a Provisional Order. A similar notice was also received from Crompton and Co. The matter was referred to the Gas, Water, and Lighting Committee.

Reading.—At the last meeting of the Town Council the Town Clerk submitted notices received by him of intention to apply to the Board of Trade for Provisional Orders, namely, from the South of England House-to-House Electricity Company, from the Electric Construction and Maintenance Company, and from the promoters of a company intended to be formed.

Arbroath.—At a meeting of the Corporation, held on Tuesday last week, the Clerk submitted an intimation by the Scottish House-to-House Electricity Company to the effect that the Company intended to apply for a Provisional Order, and soliciting the consent of the Corporation to the application. The application was remitted to the Committee of Management to consider and report.

Preserving Milk by Electricity.—M. Maisonhaute, says the *Bulletin International de l'Electricité*, having noticed that the passage of a current of electricity through milk retarded the formation of cream, made a series of experiments to see whether milk could be kept fresh in this manner. The result of these experiments is a patent for the preservation of milk by means of either static or current electricity.

Genoa.—The work in connection with the electric lighting of the principal streets and squares of Genoa is now approaching completion. The lighting will be effected by 108 12-ampere arcs, arranged on three circuits, each 5 kilometres long. The conductors are all of electrolytic copper, 3·5 millimetres in diameter, and are run overhead. The contractor, M. Albert Preve, has obtained the concession for the public lighting only for five years.

The New Companies.—According to a table just published by the *Investors' Guardian*, the capital of the electrical companies registered during the first six months of 1889 amounted to £3,563,600, as against £2,254,000 and £1,047,000 for the first six months of 1888 and 1887 respectively. The above figures do not include the registered capital of new telephone companies, which amounted during the first six months of the present year to £250,000.

Salford.—The application of the Manchester House-to-House Electricity Company for the consent of the Town Council to their electric-lighting schemes has been considered by the Parliamentary Sub-Committee of the Salford Council. The Committee have decided to recommend the Council to oppose this scheme, and secondly, to apply under the Electric Lighting Acts for powers enabling the Council to supply electricity for lighting purposes within the borough.

Maidstone.—The Maidstone Gas Company has refused to accede to the petition of the local authorities to reduce the price of their gas for public lighting, and consequently the Local Board have appointed a committee to consider the proposals of the Municipal Electric Light and Power Corporation, the Electric Construction and Maintenance Company, and the South of England House-to-House Electricity Company, who have given notice of intended application for Provisional Orders.

"The Electrician" Dinner.—The annual dinner of the proprietors and staff of *The Electrician* Printing and Publishing Company took place on Monday last. Last year's visit having proved a success, the party again went to Ightham, near Sevenoaks, where a pleasant day was spent, the weather being fine and agreeable. Dinner was provided at the "George and Dragon," where, soon after three o'clock, about 70 guests sat down, Sir John Pender, K.C.M.G., presiding, supported by Sir James Anderson.

Withington.—At a recent meeting of the Withington Local Board communications were received from the Anglo-American Brush Electric Light Corporation and the Manchester House-to-House Electricity Company, informing the Board that it was their intention to apply for Provisional Orders for the lighting of Withington. The Clerk was instructed to reply that while

Digitized by Google

the Board was not opposed to the introduction of the electric light, they could not at once consent to the applications, and asked for further particulars.

Johnstone.—At the last monthly meeting of the Johnstone Town Council a letter was read from the secretary of the Scottish House to-House Electricity Company, asking the consent of the local authority to an application to the Board of Trade for a Provisional Order to supply electricity to the town. It was agreed to refuse consent. A special meeting of the Town Council was decided upon to take the whole question into consideration as to the propriety of making application for power to provide electricity so far as they may be requested to do so.

Electric Tramways in Australia.—The Sandhurst and Eaglehawk Electric Tramway Company (Limited), formed for the purpose of putting down a tramway and working it electrically, have entrusted the work to Messrs. Booth, Ellson and Co., electrical engineers, of Melbourne, who have placed the order for the plant for the charging station with the Anglo-American Brush Electric Light Corporation (Limited), who will also supply the cars, motors, and accumulators. It is expected that the first section of the work—a line five miles in length—will very shortly be in operation.

Falmouth.—At a recent meeting of the Falmouth Urban Sanitary Authority, a letter was read from the Falmouth Gas, Coal and Coke Company, stating that, subject to the approval of the shareholders, the directors intended to apply for the necessary license and authority to supply the Authority's district with electricity. The Clerk then read similar applications from the Devon and Cornwall Electricity Supply Company and the Electric Construction and Maintenance Company. It was decided that the letters be acknowledged, and that they be considered at the next meeting.

A Locomotive in Motion Struck by Lightning.—The remarkable incident of an express train being struck by lightning while moving at the rate of thirty miles an hour recently occurred, says the *Scientific American*, on the New York and New Haven Railway, at Stamford, Ct., durmg a heavy thunderstorm. It was shortly before four p.m., as the train was whirling through the town, that a tremendous flash of lightning struck the centre of the locomotive. Both the driver and fireman were half stunned, and the engine was so disabled that another one had to be substituted.

Southampton.—At the last meeting of the Town Council, Messrs. Sharp, Harrison, Turner and Turner wrote, giving notice that the Southampton Electric Lighting and Power Company proposed to make application for a Provisional Order. There was also a similar notice from the Electric Construction Company and a further notice from the South of England House-to-House Electricity Company. The first letter was referred to the Special and General Works Committee, but the Council did not think it desirable to refer the other letter to Committee, already having entered into an arrangement with the first-mentioned company.

Cambridge.—At the last meeting of the Cambridge Improvement Commissioners notices were served upon the Clerk of the intention of the undermentioned companies to apply for Provisional Orders for supplying electricity within the district of the authority:—The Cambridge University and Town Electric Lighting Company, the Electric Trust, the Midland House-to-House Electricity Company, and the Electric Construction and Maintenance Company. It was agreed that the matter should be referred to the Paving, Drainage, and Lighting Committee, and that they should also inquire whether it was desirable that the local authority should take it in hand themselves.

Hove.—At a recent meeting of the Works and Improvements Committee of the Hove Commissioners, the Town Clerk reported the receipt of notices of intention to apply for Provisional Orders from the Brighton and Hove Electric Lighting Company, the Electric Construction and Maintenance Company, and one on behalf of a Company yet to be formed. It was decided that the Town Clerk should be instructed to place himself in communication with Messrs. Sharpe, Parker, and Co., parliamentary agents, in order that proceedings might be taken for obtaining for the Commissioners a License or Provisional Order, as may be advised, for the supply of electricity within the town of Hove.

The Inspection of Electrical Installations on Board Men of War.—An order has just been issued by the Admiralty to the effect that the electrical fittings of all ships are to be inspected and tested by the Steam Reserve and Dockyard officials as soon as a ship is commissioned. This is to be done in the presence of officers from the Departments of the Directors of Naval Ordnance and Construction, and also of the officers and men of the ships, in order that they may see everything is in perfect order and become familiar with the electric installation worked at its full power by the Dockyard and Steam Reserve officials, and to prevent any subsequent conflict of opinion in case of any mishap when on actual service.

The Barking-road Electric Cars.—On Monday evening last a defective driving-switch on one of the Barking-road cars short-circuited the battery of accumulators (100 volts) just as the driver, after putting down the passengers at Green Gate, Plaistow, was taking the car on to the stand previous to leaving for Canning Town. The instantaneous combustion of the insulation of the cable and evolution of gases from the passage of so great a current produced an explosion which lifted the seats and shattered the glass of all the windows on each side of the car. No damage was done to the electrical equipment, save the destruction of the insulation of 20ft. of 19/18 cable, as it was protected by suitable cut-outs.

Mansion Lighting.—Messrs. Drake and Gorham have at present several orders for house lighting on hand, amongst which is the new mansion now being built for B. Freeman Mitford, Esq., where there will be 300 lights in all, supplied by two 8 horse-power Marshall engines and two 10 horse-power Cornish boilers. The same firm are also fitting Alnwick Castle, the Duke of Northumberland's seat, with the electric light. The power is to be obtained from the river by means of a turbine placed half a mile from the castle. This will drive an Elwell-Parker dynamo of 18 units capacity for the charging of accumulators placed in one of the outbuildings of the castle. There will be upwards of 300 lights in the first instance.

Electric Tempering.—The practical results of the application of electricity to tempering of steel are said to have been very satisfactory both in regard to the cost and also uniformity of the product, as well as its application to tempering lower grades of steel into good spring steel. A plant where this tempering process is used on a large scale is able to temper 1,200ft. of steel wire, No. 18 Birmingham wire gauge, per hour, with an expenditure of one horse-power. It is also used to harden or to harden and temper wires, as a different disposition of the current enables one to harden the surface, producing a result comparable to case-hardening; and Bessemer steel, containing one-half of one per cent. of carbon, can be tempered into spring wire, not, however, free from all brittleness.

Electric Traction on the Underground Railway.—At the half-yearly meeting of the shareholders of the Metropolitan Railway Company on Friday last, the Chairman said, in reply to a shareholder, that with regard to electric traction the Board had concluded an arrangement by which a very important experiment would be made at the expense of the inventor. The arrangement with Lord Bury's company did not come to anything. A good many experiments were made, but they found afterwards that they were made on wrong principles. The experiments the company were now going to try would be on the direct-current system, and it was proposed to try it on the omnibus part of the railway. It was a matter that the Board were convinced could be done some day, but, as with the locomotive itself, they would have to go through many painful and fruitless experiments.

The Germain Dry Battery.—A dry cell presenting some novel features has lately been brought out by M. P. Germain, belonging to the French telegraph service. The material employed by M. Germain is cellulose, prepared from cocoanut fibre. This material is cheap, is a good conductor, and possesses great absorptive properties. In the Germain modification of the

Digitized by Google

Leclanché cell, the carbon plate surrounded by a mixture of powdered retort carbon and binoxide of manganese rests underneath a cellulose pad soaked with a solution of sal ammoniac; on the top of the cellulose there are two sheets of zinc. Four powerful springs press the cellulose pad tightly against the layer of carbon. Laboratory tests show that this cell does not polarise nearly as rapidly as the Leclanché, and is capable of giving comparatively powerful currents for short periods. The E.M.F. of the cell is 1·5 to 1·6 volts.

The Electrical Industry in Spain.—The efforts of Spanish electricians to advance the industry without the assistance of foreign makers, do not, says the *Manchester Guardian*, appear to have been at all satisfactory. Our contemporary quotes advices from Madrid to the effect that the "Sociedad Española de Electricidad" has been obliged to enter into an arrangement with an English firm in order to continue its operations, and it refers to the probability of the "Sociedad Matritense de Electricidad" being obliged to make similar arrangements with foreign houses. Much regret is expressed at this state of affairs, and the *Economista* of Madrid in referring to the subject remarks:—"It is truly lamentable that a company, such as the Española, which was founded in a spirit of the purest patriotism, with the object of constructing its own machinery, and of using native-made motors, should now have to hand over its business to foreign makers, whose first object will be to prevent the manufacture of electrical machinery in Spain."

Severe Thunderstorms.—Although several violent thunderstorms have occurred during the past few days in various parts of the United Kingdom, and reports still come to hand of the damage done by lightning in the storms of last week, no accidents of a fatal character are recorded. On Tuesday, Wath was visited by a severe thunderstorm, the lightning striking the signalling instruments on the Midland Railway, and the block system had to be suspended. On Sunday a house at Lincoln was struck by lightning and greatly damaged. Last week, at Ipswich, Saffron Walden, Stowmarket, Felixstowe, and Colchester, several buildings were struck, and in many instances suffered considerable damage. At Flint, Huntley Lodge had the roof shattered and the chimneys torn down. At Dumfries, Marchfield House, which is about one and a-half miles from the town, was injured. The lightning struck a vane on the top of a square tower and wrenched a number of large stones from their position, scattering them around the building and breaking several holes in the roof. Another flash entered a detached dwelling at the back, displacing some masonry.

The American "Ball" Electric Lighting Company in Paris.—A correspondent writes as follows:—"In view of the neighbouring successful installations throughout Paris, it seems a pity that the success of Buffalo Bill's Wild West Show at Neuilly should be jeopardised by the uncertainty of its lighting arrangements. For the night of the 11th inst. a grand benefit representation was advertised, including '*Brilliant éclairage electrique par les nouveaux appareils Américains de Ball.*' Many thousands were present at the arena, including Government and local dignitaries; the Indians were engaged in deadly conflict, when suddenly every lamp was extinguished. The performance was stopped and some confusion prevailed amongst the audience, but they were kept seated for about ten minutes, when the light again appeared. Not for long, however, for after flickering and struggling for some time the *nouveaux appareils* again failed, the light expired, and the show broke up. Happily the people preserved good temper throughout, and a brilliant moon, in dispersing them, formed a reliable and efficient substitute for the vacillating arc. If the Ball Company of New York had anything to teach, the transport of a plant across the Atlantic might not seem the straining of a point. But to fail ignominiously at a crucial moment, side by side with that model of arc-lighting, the St. Lazare Railway Terminus, suggests the importation of coals to Newcastle, and very bad coals into the bargain, which it is strange that Buffalo Bill's directors do not recognise."

Curved Electrotypes.—A method, says *Invention*, has been devised in the United States for securing in the process of electrotyping a curved metallic shell of uniform thickness. This is done by the use in the electrotype bath of a curved matrix formed upon a curved elastic plate, and a curved soluble anode suspended at a uniform distance therefrom, the curvature of the anode conforming to that of the matrix, so that when placed in position for the electro-deposition of metal an equal space can be maintained between all parts of the concave surface of the matrix and the convex face of the anode plate. The curved matrix is formed by the use of a curved elastic plate, preferably of thin sheet metal, held in a flat position by a suitable clamping device. While so held, the face of the plate is covered with a layer of moulding wax or other moulding composition. The face of the wax is properly black-leaded, after which an impression of the type form is taken thereon, and the matrix withdrawn from the form, black-leaded, trimmed, built up, &c. When these operations have been performed, and the matrix perfected in every detail, the elastic plate upon which the matrix has been formed is released from it clamping bed and at once returns to its original curvature. The result is a curved matrix, which, after the usual treatment, is ready for the bath. In printing, an electrotype plate is superior to a stereotype, the copper forming its face being harder and more durable than type metal. Its use, however, on cylindrical presses has been regarded as objectionable, because of the difficulty attending the formation of a true curvature of the copper shell. The practice hitherto has been to first secure a copper shell from a flat matrix, and then bend the shell to the required curvature. The bending requires great skill in the handling and manipulation of the shell, the sharp angles and varying faces of the type rendering it liable to crack or bend irregularly, either of which would make it worthless. The method described is said to do away with the necessity, and, consequently, the danger of bending the shell, as it comes from the bath curved as required for the press cylinder, and in condition for immediately undergoing the usual process of tinning, backing, shaving, and trimming.

The Electric Lighting Bills.—On Friday last, on the motion to read the Electric Lighting Provisional Orders (No. 1) Bill a third time, Sir G. Campbell asked whether the Corporation of Birmingham had given their consent to the Provisional Order relating to the city in an express and direct form. Sir M. Hicks-Beach said he entirely repudiated the policy which the hon. member attributed to the Board of Trade of disregarding the wishes of the local authorities in this matter. He might say that only this Session he had overruled a report made by an officer of the Board of Trade in favour of a Provisional Order in a very important case, because the consent of the local authority had been refused. The Corporation of Birmingham were able to take care of themselves. They were represented by as many as nine members in that House, and this Bill had passed through all its stages without a word of objection from any one of them. More than that, communications had passed between the Board of Trade and the Birmingham Corporation which showed ample evidence of the fact that the Corporation were consenting parties to the Bill. He admitted that they had not in so many words recorded their assent; but they had intimated their willingness to do so; and it would no doubt shortly be received at the Board of Trade. The Bill was then read a third time.—On Tuesday last, on the motion of Mr. H. Gardner, in the case of the Metropolitan Electric Supply Bill, Standing Orders were suspended, and the Bill was taken into consideration, and read the third time. On the consideration of the Electric Lighting Provisional Orders (No. 2) Bill, Mr. Bartley moved the following clause:—"Nothing in this Order shall affect the right of any person to supply his own premises and any houses or premises adjacent with energy." Sir M. Hicks-Beach said he had looked into the matter, and there was no doubt whatever that the provisions of the Bill would in no way interfere with or take away the rights of individuals which the hon. member referred to. Mr. Bartley then withdrew the clause. Mr. Baumann moved the amendment he had been precluded from moving earlier, to reduce from three years to two years the period for which consumers were to be bound in unscheduled streets. Sir M. Hicks-Beach accepted the amendment, and said he would see that the consequential amendments were made in another place. The amendment was agreed to, and the Bill was read a third time.

ON THE DISTRIBUTION OF CONTINUOUS ELECTRIC CURRENTS BY MEANS OF CONDENSERS.—II.*

BY DR. STEPHAN DOUBRAVA.

At the close of my first article I pointed out the fact that by letting the charging and the discharging circuits coincide, the loss of energy in transformation may be greatly reduced. Such an arrangement would not, however, be sufficient, for the simple reason that the energies contained in the charging and discharging waves would distribute themselves according to the resistances. We could, therefore, by the use of condensers with current of more or less high tension, feed incandescent lamps in multiple arc, but nothing would be saved in the conductors. In order to economise in the main leads, the distribution of the energies must be altered by introducing self-induction.

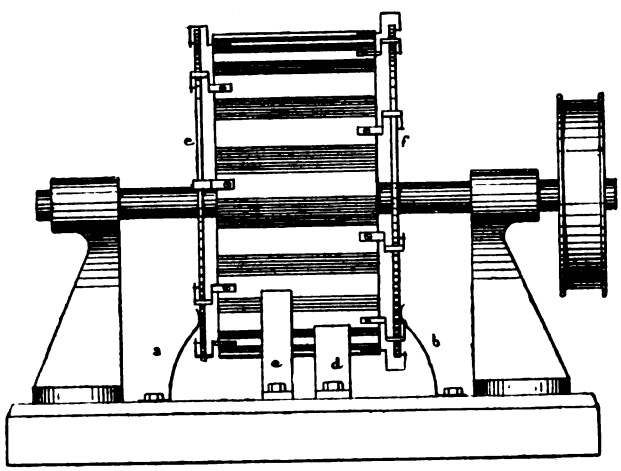

FIG. 1.—The Disjunctor.

In my system the continuous current is led to certain points, where, by means of a disjunctor or commutator, represented in Fig. 1, it is transformed into electric waves, which are used to charge the condensers. This is effected without the slightest sparking, as will presently be made clear. The whole arrangement is diagrammatically shown in Fig. 2, from which it may be seen that the circuits are not metallically closed, but are kept open by the condensers.

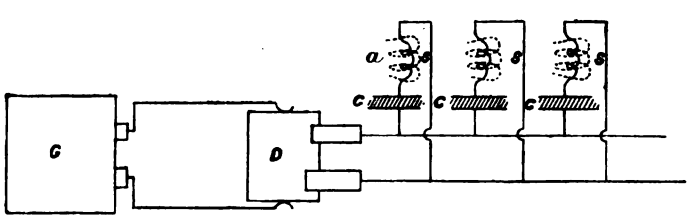

FIG. 2.

G, generator; *D*, disjunctor; *C*, condenser; *a*, primary coils; *s*, secondary coils.

The disjunctor, which was driven in my experiments by a small dynamo of about ½ horse-power, is made of metallic strips, which are separated from each other by strips of non-conducting material. The former are connected alternately to two metallic discs, *e*, *f*. To the latter the main current is conveyed by means of two sliding contacts, *a* and *b*. When the disjunctor is revolving the strips pass under two brushes, *c*, *d*, which are placed in such a manner that they cannot touch one and the same metallic strip simultaneously, and that after leaving two strips they both touch for a certain time the adjacent insulating strips. The brushes are connected with the condensers.

Now, when the disjunctor is turning, the following operations are performed:—Suppose the brushes are touching two metallic strips. Then a current wave is led to the condenser, which will last till the latter has reached the potential difference of the generator. This being the case, the brushes may now safely leave the strips *without any sparking at all*. In this way I have succeeded in breaking circuits of 500 and even more volts without sparking. The brushes having left the metallic strips touch now for a certain time upon the insulation; then again two strips will come in contact with them. But now these strips are in connection with the opposite pole of the generator; therefore a new current wave, but the opposite in direction to the former, will pass to the condenser. This first discharges the latter, and then charges it in the opposite sense till the condenser has again reached the potential difference of the generator. Then again the brushes will move from the strips without sparking, and so on. It may be easily seen that in this way no direct connection between the poles of the generator is possible.

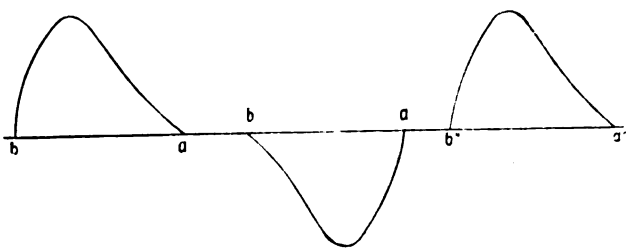

FIG. 3.

The fluctuation of the current in that part of the circuit which lies between the disjunctor and the condenser is represented by diagram Fig. 3. Of course the interruptions must take place only between the points $a\,b'$, a', b'' . . . but never between the points $a\,b$, $a'\,b'$. . . . . Fig. 4 shows the current in that part of the circuit which lies between the generator and the disjunctor, that is in the main conductor.

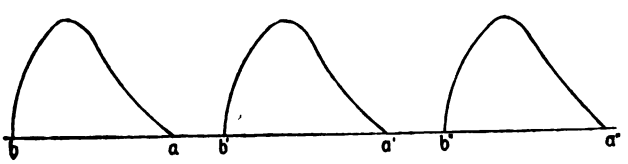

FIG. 4.

It will be easily understood that this current may be made approximately continuous simply by attaching a suitable commutator to the shaft of the disjunctor and connecting the lamps in parallel. In this case each branch contains a condenser, and is in connection with the disjunctor by means of two brushes. Then the charging of the condensers takes place successively, and the current in the mains will appear as represented in Fig. 5.

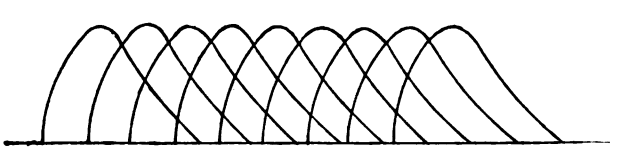

FIG. 5.

With the arrangement described, a number of reversals may be produced far exceeding that of an alternate-current dynamo. For instance, I have used 900—1,500 reversals per second. By this means it is possible not only to attain an efficiency of upwards of 97 per cent., but also reduce the material used for the transformation of the current to the least amount. The condenser required per 16 candle-power lamp need only be 1 square metre area, and the induction coil 0·6 kilogramme (total weight).

I will now establish the theory of the system described.

We may begin time-counting from that moment when the potential difference of the condenser changes from +E to −E, and we denote by

* *See* Article I., *The Electrician*, April 19, p. 676.

Digitized by Google

r the total resistance of the charging circuit,
R the total resistance of the secondary circuit,
F the capacity of the condenser,
p its E.M.F. at the time t,
E the E.M.F. of the generator,
l and L respectively, the coefficients of self-induction in the primary and secondary windings of the induction coil,
m the coefficient of their mutual induction,
c and C respectively, the currents in the primary and secondary circuits.

We have then

$$c = -F\frac{dp}{dt} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$cr = p - (-E) - l\frac{dc}{dt} - m\frac{dC}{dt} \quad . \quad . \quad . \quad . \quad (2)$$

$$CR = -L\frac{dC}{dt} - m\frac{dc}{dt} \quad . \quad . \quad . \quad . \quad (3)$$

From (1) and (2) follows by differentiation

$$r\frac{dc}{dt} + l\frac{d^2c}{dt^2} + m\frac{d^2C}{dt^2} + \frac{c}{F} = \theta \quad . \quad . \quad . \quad (4)$$

The partial integrals of (3) and (4) are respectively

$$c = \alpha e^{\alpha t}; \quad C = A e^{\alpha t},$$

where $$A = -\alpha\frac{m\alpha}{R + L\alpha} = \alpha f(\alpha),$$

and $$\left.\begin{aligned}(lL - m^2)\alpha^3 + (lR + Lr)\alpha^2 + \left(\frac{L}{F} + Rr\right)\alpha \\ + \frac{R}{F} = \theta\end{aligned}\right\} \quad . \quad (5)$$

Denoting the roots of the latter by α_1, α_2, α_3 we get

$$\left.\begin{aligned}c &= a_1 e^{\alpha_1 t} + a_2 e^{\alpha_2 t} + a_3 e^{\alpha_3 t} \\ C &= a_1 f(\alpha_1) e^{\alpha_1 t} + a_2 f(\alpha_2) e^{\alpha_2 t} + a_3 f(\alpha_3) e^{\alpha_3 t}\end{aligned}\right\} \quad . \quad (6)$$

By the simultaneous values $t = \theta$; $c = \theta$; $C = \theta$; $p = E$, we obtain

$$\left.\begin{aligned}&a_1 + a_2 + a_3 = \theta \\ &a_1 f(\alpha_1) + a_2 f(\alpha_2) + a_3 f(\alpha_3) = \theta \\ &a_1\alpha_1 + a_2\alpha_2 + a_3\alpha_3 = \frac{2EL}{lL - m^2}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (7)$$

from which the values of the constants a_1, a_2, a_3 are obtained. These give

$$c = \frac{2E}{\chi^{(\alpha)}(m^2 - lL)}\left[(R + L\alpha_1)(\alpha_3 - \alpha_2)e^{\alpha_1 t} + (R + L\alpha_2)(\alpha_1 - \alpha_3)e^{\alpha_2 t} + (R + L\alpha_3)(\alpha_2 - \alpha_1)e^{\alpha_3 t}\right]$$

$$C = \frac{2Em}{\chi^{(\alpha)}(m^2 - lL)}\left[\alpha_1(\alpha_2 - \alpha_3)e^{\alpha_1 t} + \alpha_2(\alpha_3 - \alpha_1)e^{\alpha_2 t} + \alpha_3(\alpha_1 - \alpha_2)e^{\alpha_3 t}\right]$$

where $\chi^{(\alpha)} = \alpha_1\alpha_2(\alpha_1 - \alpha_2) + \alpha_2\alpha_3(\alpha_2 - \alpha_3) + \alpha_3\alpha_1(\alpha_3 - \alpha_1)$.

$[\chi^{(\alpha)}]^2$ is a symmetrical function of the roots, and it can therefore be expressed as known by the coefficients of equation (5).

Let T denote the time necessary to charge the condenser completely; the energy given out by the generator during that time is $2E^2F$, and the energy used up in the secondary circuit is

$$\int_0^T C^2 R\,dt;$$

therefore the efficiency $N = \dfrac{\int_0^T C^2 R\,dt}{2E^2F}$.

Now for all $t > T$ we have always $C = \theta$, and we may write

therefore $\int_0^T C^2 R\,dt = \int_0^T C^2 R\,dt + \int_T^\infty C^2 R\,dt = \int_0^\infty C^2 R\,dt =$

$$-R\left(\frac{2Em}{\chi^{(\alpha)}(m^2 - lL)}\right)^2\left\{\frac{a_1^2(\alpha_2 - \alpha_3)^2}{2\alpha_1} + \frac{a_2^2(\alpha_3 - \alpha_1)^2}{2\alpha_2} + \frac{a_3^2(\alpha_1 - \alpha_2)^2}{2\alpha_3} + 2\frac{a_1a_2(\alpha_2 - \alpha_3)(\alpha_3 - \alpha_1)}{\alpha_1 + \alpha_2} + 2\frac{a_2a_3(\alpha_3 - \alpha_1)(\alpha_1 - \alpha_2)}{\alpha_2 + \alpha_3} + 2\frac{a_3a_1(\alpha_1 - \alpha_2)(\alpha_2 - \alpha_3)}{\alpha_3 + \alpha_1}\right\};$$

or, by representing $\chi^{(\alpha)}$ and the expressions in the brackets as functions of the coefficients of equation (5),

$$\int_0^\infty C^2 R\,dt = \frac{2E^2F}{1 + \frac{r}{R}\left(\frac{L}{m}\right)^2 + \frac{rF}{m^2}(lR + Lr)}.$$

Therefore, $$N = \frac{1}{1 + \frac{r}{R}\left(\frac{L}{m}\right)^2 + \frac{rF}{m^2}(lR + Lr)}.$$

By that it is seen that if r—the resistance of the main conductors—is increased, we may always arrive at any desired efficiency by properly choosing the other values, R, L, m, F, l.

THE EFFICIENCY OF A TRANSFORMER.

BY T. SPENCER.

The following method of obtaining the efficiency of a transformer is, I believe, novel, and it would seem to have a considerable advantage over the calorimetric method on account of its simplicity.

Moreover, it is not difficult to see that this method should give accurate results, for it takes into consideration all the different effects such as hysteresis and Foucault currents, periodicity and form of alternation, for all the effect that these things could possibly have is to vary the number of lines of force which pass through the coils at any time. The only assumption which is made is that all the lines which pass through the primary pass through the secondary, which, considering that all transformers are made with a closed magnetic circuit, and also with their primary and secondary very close together, may be considered as strictly true.

Let us write—

c The current in amperes at the time t in the primary.
c' That at the same time in the secondary.
e The E.M.F. at the same time at the terminals of the primary in volts.
r The resistance in ohms of the primary.
r' That of the secondary.
R = The resistance of the secondary circuit which is outside the transformer; it is supposed to have no self-induction in this investigation.
n = The number of lines of magnetic force passing through the coils.
L = A quantity proportional to the number of turns of wire in the primary.
L′ = The same for the secondary.

The last two of the above quantities are supposed to have the proper signs to make the following equations correct. It is not easy to see just what signs they should have, but as in the final result these quantities appear as their squares, a knowledge of their signs is not required.

Now by Ohm's law, and the principle of Maxwell, we have at the instant of time dt the two following relations:

for the primary $$cr = e + L\frac{dn}{dt},$$

and for the secondary

$$c'(R + r') = L'\frac{dn}{dt}.$$

Eliminating $\frac{dn}{dt}$ from these two equations we have

$$cr - e = \frac{L}{L'}c'(R + r'),$$

but $\frac{L}{L'}$ is equal to the constant of the transformer numerically.

Writing m for this we have

$$cr - e = mc'(R + r').$$

Squaring both sides of the equations, and transposing, we have

$$ce = \frac{c^2r}{2} + \frac{e^2}{2r} - \frac{m^2(R + r')}{2r}c^2(R + r').$$

Digitized by Google

Multiply all through by dt, and integrate between the limits of zero and unity, we have—

$$\int_0^1 c\,e\,dt = \frac{1}{2}\int_0^1 c^2 r\,dt + \frac{1}{2}\int_0^1 \frac{e^2}{r}dt - \frac{m^2\,(R+r')}{2r}\int_0^1 c^{2'}\,(R+r')\,dt.$$

Now the expression on the left-hand side of the equations represents the total amount of energy which has been absorbed by the transformer in one unit of time.

Now, if we put in the right-hand side of the equations,

$$C_2 r = \int_0^1 c^2 r\,dt,\quad c^{2'}(R+r') = \int_0^1 c^{2'}(R+r')\,dt,\quad \text{and}\quad \frac{E^2}{r} = \int_0^1 \frac{e^2}{r}\,dt,$$

we have—

$$\int_0^1 e\,c\,dt = \frac{C^2 r}{2} + \frac{E^2}{2r} - \frac{m^2\,(R+r')}{2r}\,C^{2'}\,(R+r').$$

Now, it is evident that C, C′, and E are the values of the currents and E.M.F. which we should read from our instruments if they were placed in the two circuits. For what we mean by a volt or ampere in dealing with the alternating system is that pressure or current which when applied to a conductor would heat it, the same as a volt or ampere of direct current would do.

Now, the energy which is being recovered from the transformer as useful energy is that which is being dissipated in the resistance R as heat—that is, $C^{2'}\,R$.

Dividing this by the total energy entering the transformer—that is,

$$\frac{C^2 r}{2} + \frac{E^2}{2r} - \frac{m^2\,(R+r')}{2r}\,C^{2'}\,(R+r'),$$

we have, after reducing, the efficiency equal to

$$\frac{2r\,R\,C^{2'}}{C^2 r^2 + E^2 - m^2\,(R+r')\,C^{2'}}.$$

THE MANDROUX PORTABLE TESTING APPARATUS.*

M. Mandroux, well known for his improvements in telegraphy and telephony, has recently devised a very compact set of portable testing apparatus, comprising a galvanometer, a dial pattern resistance-box, a condenser, battery, and several varieties of keys. One of the objects which M. Mandroux had in view was to make the connections as simple as possible, and enable the operator to change from one test to another by merely altering a plug. In addition to achieving this result in a very successful manner, M. Mandroux has introduced several interesting improvements into the various parts of the apparatus.

The galvanometer (Fig. 1) has a double needle consisting of two strips of steel joined together as shown, in the shape of an X. These two needles being oppositely magnetised the system is rendered astatic, and thanks to their peculiar X shape the deflections of the instrument are practically proportional up to 25deg. Owing to the great breadth of the needles the damping effect of the air renders the galvanometer very dead-beat. The suspensory arrangement permits the use of large, strongly-magnetised needles, rendering the sensitiveness of the instrument very great. As the galvanometer is intended to undergo considerable rough usage, M. Mandroux includes in each set of apparatus a box of 15 ready-prepared cocoon fibres. These fibres are cut to the required length and are provided at either end with a small aluminium ring. When replacing a broken fibre the only thing to be done is to pass one ring over the hook at the top of the instrument, and the fibre which is kept stretched by the weight of the lower ring can then be easily passed down the tube and attached to the hook belonging to the needles.

The resistance-box (Fig. 2) is of the dial pattern, in which the dial plugs are replaced by a peculiar form of switch. The contact pieces and the centre piece are turned so as to make the space between them a V-shaped groove. A sliding wedge-shaped contact moved by a small handle, the axis of which coincides with the centre of the central block, fits into this groove, and to ensure good contact it is pressed well into its place by a powerful spring. Resistances can, therefore, be cut in or out without breaking the circuit, as is the case whenever a plug is moved in the older form of dial pattern resistance-box. Each of the four dials has its own switch, and the four switches are all mechanically connected by means of a Maltese cross arrangement, analogous to that employed in some electricity counters, each complete circle performed by the switch of one dial causing that of the next dial on the left to move one unit. Thus, ten revolutions of the switch of the unit dial makes the switch of the ten dial move once round the circle. This movement takes place backwards or forwards, according as the unit switch is moved in one direction or the other. As it would be a great drawback to be obliged to move the thousand and the hundred dial by means of the unit switch, M. Mandroux has a device by means of which any one of the dial switches can be rendered independent of the ones on the right of it. It is only necessary to press on the handle of the switch in order to lift a pin, which penetrates into one of the ten holes of a small disc, which is in mechanical connection with the Maltese cross. When the handle

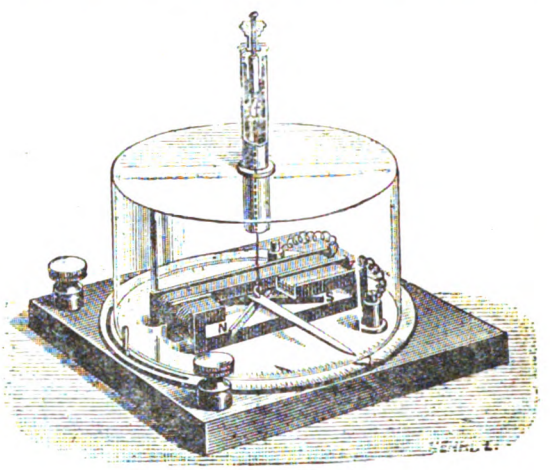

Fig. 1.—The Mandroux Astatic Galvanometer.

is no longer pressed the switch is immediately thrown into gear again. The introduction and suppression of resistance is therefore continuous, and the needle does not undergo any sudden and violent jerks due to the breaking of the circuit.

The condenser presents peculiarities only in the mode of construction. Each sheet of mica, after having been carefully wiped and dried, is gently heated and covered with five or six layers of shellac varnish. The sheets are then dried in a stove for some three hours, the heat being moderate and constant. When the mica is dry enough the condenser is built up in the usual manner, care

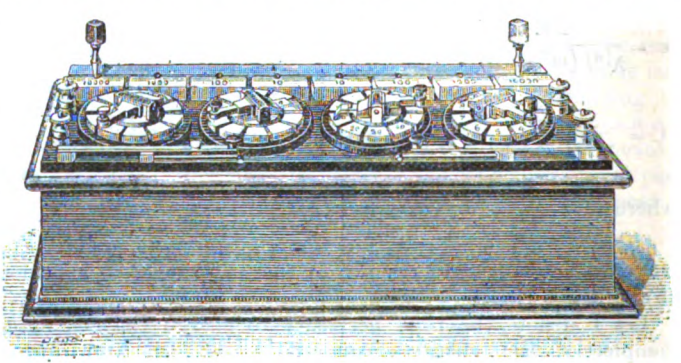

Fig. 2.—The Mandroux Dial Pattern Resistance Box.

being taken to perform this operation on a clean sheet of iron, which is kept slightly hot. When the required number of layers of mica and tinfoil has been reached, the whole, while still hot, is placed in a press and is cooled under strong pressure. The following instance will give an idea of the results obtained by this process. A condenser with 100 non-varnished mica sheets, built up in the ordinary manner, had a capacity of ·35 microfarads and an insulation resistance of 800 to 1,000 megohms. When this condenser was pulled to pieces and reconstructed as indicated above, its capacity had only diminished by ·02 microfarads while its insulation resistance had increased to 15,000 megohms.

The reversing key devised by M. Mandroux is also distinguished from that in ordinary use by an important improvement. Instead of the ebonite clamp usually employed to keep the key down, M. Mandroux provides the keys with two small projections. When one key is depressed, it presses against a small knob at the end of flexible strip of metal, the projection is caught in a small notch in

* Extracted from *La Lumière Électrique*.

Digitized by Google

the knob, and the key is kept down. On depressing the second key, it is caught in the same way, but not before it has released the first.

By means of the Mandroux apparatus all the tests required in ordinary telegraph work can be taken on the spot, and the various improvements introduced will probably cause it to be used in laboratories and elsewhere.

THE PROPOSED GOVERNMENT STANDARDISING LABORATORY.

The following circular has been issued by the London Chamber of Commerce, at the instance of the Board of Trade, with a view of ascertaining the probable amount of support that a Government Standardising Laboratory would meet with from the electrical industry :—

"Dear Sir : The Board of Trade desires to avail itself of the organisation of the London Chamber of Commerce for the purpose of ascertaining the probable extent to which a Government Laboratory for standardising electrical instruments would be used :—

(*a*) By supply companies for the certification of meters, voltmeters, and ammeters, and

(*b*) By manufacturers of electrical instruments.

Your replies to the accompanying questions are therefore requested. The individual replies will be considered as confidential, and only the aggregates will be published.—Yours, faithfully,

Kenric B. Murray, Secretary.

1. Supposing a standardising laboratory to be ready at the commencement of the year 1890, how many ordinary house meters do you expect to send in for certification ?
2. How many ammeters do you expect to send in ?
3. How many voltmeters do you expect to send in ?
4. State whether you send in as an undertaker or as a manufacturer ?"

The following addendum has been sent to certain manufacturers and agents, with the view of avoiding duplicate returns relating to the same instruments :—

"Please take precautions in sending your replies to the circular against possible repetitions of the same instruments by manufacturer and agent, or supplier, *e.g.*, yourself and....."

STANDARD TYPES OF APPARATUS.

The following circular has been issued by the Committee of the Electrical Section of the London Chamber of Commerce to all members of the Section :—

"Sir : The Sub-Committee appointed by the General Committee of the Electrical Section of this Chamber to consider the recommendation of standard or uniform types desire to obtain information as to the extent to which the British Association Screw Thread has been adopted by the electrical trade up to the present. No steps have been taken by the British Association to bring their standard screw gauge before the trade other than the publication in their 1884 (Montreal) Report of the report of their Committee. This Committee consisted of Sir Joseph Whitworth, Sir William Thomson, Sir F. J. Bramwell, Mr. A. Stroh, Mr. Beck, Mr. W. H. Preece, Mr. R. E. Crompton, Mr. E. Rigg, Mr. A. Le Neve Foster, Mr. L. Clark, Mr. E. T. Wood, and Mr. Buckney, and were 'appointed for the purpose of determining a gauge for the manufacture of the various small screws used in telegraphic and electrical apparatus, in blockwork, and for other analogous purposes.' In the Report of the British Association for 1885 (Aberdeen) it is stated that the standard screws 'have been officially adopted by the telegraph department of the Post Office, and this step alone may be relied upon to ensure their general adoption by the telegraphic and electric instrument trades in the course of a few years.' In the 1887 (Manchester) Report the following statement was made by Mr. Preece :—'Owing to the large number of telegraph instruments made by different manufacturers, the number of screws of different forms and sizes in use was very great, and this was found to be a great disadvantage and a great source of expense. When the Post Office commenced to manufacture its own apparatus it was decided to make all parts to template, so as to be interchangeable, and it was also decided to adopt some standard for screws. The standard recommended by the Committee appointed by the British Association is now being introduced in all instruments and apparatus manufactured by and for the Post Office Department, a circular to that effect having been issued to all firms manufacturing for the General Post Office.' Notwithstanding the above a considerable number of manufacturers of electrical instruments are still quite unacquainted with these screws, and the Committee feeling that the practical value of such a standard depends largely, if not entirely, on the extent to which it is adopted, invite communications from the trade upon the subject, and for that purpose have drawn up a set of questions, sent herewith, to which your answers are requested. It should be noted that the enclosed questions need not entail any disclosures whatever as to the actual extent of your business ; only the proportion or percentage is asked for, but actual figures may be given. The result of the analysis of the answers to these questions will be communicated to the members of the London Chamber of Commerce, in order that those who do not use the screws may see whether their use is sufficiently general to induce them to adopt them.—Yours faithfully,

Kenric B. Murray, Secretary.

Electrical Trades' Section.

1. Do you use the British Association standard screw gauge in your manufacturing business ?
2. If so, what is the proportion of small screws of this gauge compared with other screws smaller than the Whitworth sizes used by you ?
3. Also, if so, do you find that for ordinary purposes you require to use other screws than those of the Whitworth and the British Association gauges ?
4. If you do not use the British Association screw, have you any reason other than that you do not care to incur the expense and trouble involved by their adoption ?"

PARLIAMENTARY INTELLIGENCE.

The Select Committee on the Metropolitan Electric Lighting Schemes.

Friday, July 19

The Select Committee of the House of Commons resumed consideration of the Bills on Friday under the presidency of Sir G. Trevelyan.

Mr. A. GRAY, on behalf of the Board of Trade, said the Board of Trade had power to provide for reciprocity between the local authority and the electric companies as to breaking up the streets, and they could also provide for it in the case of owners and operators in the case of the alteration of pipes, but the power to the gas company to dig trenches for electricity companies could only be given by the Committee considering the Provisional Order Bills.

On the suggestion of Mr. PEMBER, counsel retired for an hour to consult with a view to agreeing upon a clause ; on returning,

Mr. PEMBER said they had agreed to a clause providing for the reciprocity between the gas and the electric companies in digging trenches. The preamble would state that the Provisional Order had been confirmed as amended.

Mr. POPE concurred, and Mr. GRAY said of course the Committee had power to make the alteration if it thought fit.

Mr. SAUNDERS also agreed.

The CHAIRMAN said if Parliament thought it an undue provision they could strike it out.

The new clause was then read, providing for fourteen days' notice of new works and for the exercise of the reciprocity mentioned.

Mr. FREEMAN then objected that the proviso which had been inserted for the protection of the London County Council was too limited, and he proposed other words to be inserted in its place.

Some discussion took place on the point, but on an objection by Mr. FLOYD,

The CHAIRMAN said that as Mr. Freeman could not show that any power of the County Council was not gained by the original proviso, the Committee upheld that proviso.

Mr. GRAY suggested that the rights of the water companies should be protected in the same way.

Mr. SAUNDERS said that the water companies were satisfied with the clauses in the Bill, and

The CHAIRMAN said it was unnecessary.

A verbal alteration was made in the clause, which was then approved by the Committee.

The London Electric Corporation Bill was gone through and approved after alterations had been made providing that they should not acquire the undertaking of or associate themselves with any other electric company unless authorised by Parliament to do so ; that the accounts should be examined by a Board of Trade auditor ; and that they should not break up any bridge, or the approaches thereto, without the consent of the authority in whom they were vested, and in accordance with plans approved by the authority or settled by arbitration.

The other Bills having been gone through, and similar amendments inserted, the Committee closed.

At a subsequent meeting of the Committee the clauses were formally adopted, and report was made to the House.

Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

THE "SUNK" LIGHTSHIP CABLE.

The second and final Report of the Committee appointed by the Board of Trade to inquire into the desirability of Electrical Communication between Light-Vessels or outlying Lighthouses and the shore has just been published. It is, we regret to say, adverse to the proposal; but much as we desire to see a complete system of electrical communication established round the coast we cannot pretend to be surprised at the result of this particular inquiry, or very much discouraged by it. The references to which the Board of Trade restricted the Committee were extremely limited, and not of the kind which the public have been constantly demanding since the inquiry was started. The experimental telephonic cable connecting the "Sunk" lightship with the shore at Walton-on-the-Naze was the sole matter on which the Committee had to report; and the only question arising out of it was whether the cost of laying and maintaining this cable, amounting, as it appears, to nearly £5,000 was justified by the service it had rendered during the four years of its existence. Exactly two years ago the Committee finished a preliminary inquiry, recommending that before a final opinion ought to be formed on this point a further trial of eighteen months would be desirable; and now after this

Digitized by Google

interval has elapsed the opinion foreshadowed in the earlier Report has been confirmed, the Committee recommending that the service shall be discontinued. As the Trinity House authorities announce that failing the sanction of any further expenditure in respect to the experiment it will not be possible with the means left available to renew any portion of the cable should it become broken, it follows that unless private enterprise or public philanthropy now comes to the rescue the cable will soon have to be abandoned.

It will be remembered that the chief object of this inquiry was to ascertain whether electrical communication of the kind referred to would facilitate the saving of life at sea, the saving of property being a quite subordinate matter, and the further question of utilising it as a means of signalling for shipping and commercial purposes being decided in the negative on the first inquiry. There only remained, therefore, the simple question what number of lives the "Sunk" cable had been the means of saving. It happens that the past two or three years have been exceptionally free from serious storms and fogs; and it is also a fact that an additional number of lightships have latterly been established in the district, the result being that wrecks were less numerous than during former quinquennial periods, and consequently there was less need for life-saving appliances of any kind. The inevitable conclusion of the Committee under these circumstances is that "the expenditure involved is not commensurate with the advantages gained." Sir EDWARD BIRKBECK, chairman of the Royal National Lifeboat Institution, who was a member of the Committee, dissents from the Report, however, on this issue, pointing out that the information given of the exact position of the stranded vessels by means of the "Sunk" lightship telephone service has been of great value to the crews of the Walton and Harwich lifeboats, enabling them to take the most direct course to the scene of disaster, instead of having had to go in the first instance to the light-ship to obtain the necessary directions; and he recommends a further trial of at least five years, the expense to be met by an annual Parliamentary vote.

We sincerely hope that steps may be taken to induce Parliament to accede to this proposition, or to obtain the funds by national subscription until the experiment has had a fuller trial, or has been repeated elsewhere under different conditions. It appears that the "Sunk" is not the point which the best authorities would have chosen for the locality, the Trinity House expressing a decided preference for the Gunfleet Lighthouse, on account both of situation and cost. Holding this view, we could hardly expect Trinity House to favour the cable at the "Sunk;" nor can we be surprised at the members of that influential body declaring that if they have to provide the money they would much prefer to spend it on additional lights and fog signals—in other words, on appliances for preventing wrecks rather than on "what seems to them at best but the means for the occasional relief of a casualty." On the other hand, they report very favourably indeed of the cable itself, furnishing the information on which the Committee's Report on this part of the subject is founded. The words of the Report are well worth quoting, and will be borne in mind by those who are warmly advocating the extension of electrical communication for purposes of national defence and the protection of our commerce: "We are of opinion that the experiments which have been carried on since December, 1884, in connection with the 'Sunk' lightship with the mainland, have completely shown the possibility of establishing electrical communication, even in positions where, as is the case at the 'Sunk,' the condition of tides and currents, as well as the foul and rocky bottom, are most unfavourable."

This is the highest compliment that could be paid to the firm which had charge of the undertaking; for the difficulties were not so much those specifically referred to, as the more serious ones of maintaining attachment to the ship as she shifted with the sands, and of preventing fouling with her moorings as she turned with the tides. Interruptions have been rare, and always promptly repaired, generally by the men on the spot. A considerable amount of chafing to the outer armour in the vicinity of the vessel is unavoidable, and will probably always require supervision at intervals. But the experience of the past four years has pretty well defined the problem to be solved, and cable manufacturers now know exactly what provisions have to be made for keeping such connections intact. This point being settled by the experiment at the "Sunk" we have little fear that the Report upon which we have commented will seriously delay the wider schemes of electrical coast communication which the country so much desires. In this relation it is interesting to note a communication made to the Committee by the Inspector of Danish Lights, about which so much has been written. It appears that the telegraphs connected with the Danish light stations belongs to the Government system, and forms no part of the lighthouse service, although the keepers are permitted to accept and send telegrams at the usual charges. None of the Danish lightships are connected by cable, but, on the other hand, most of the "isolated island lighthouses" are connected with the mainland telegraphs, as are also most of the lifeboat and rocket stations. We need not dwell on the extreme usefulness of a service such as that, and we confidently hope that the time is not far distant when the British Isles may boast of one not inferior to it.

REVIEWS.

Electricity: Theoretically and Practically considered by the aid of Thermo-Electricity. By ARTHUR RUST. (London: E. and F. Spon, 1889.)

The writer of this pamphlet has built a thermopile containing some 6,000 elements, of which he gives the following description:—

"The heater which occupies the interior of the cylindrical arrangement of elements is a slow combustion stove of particular construction. In the centre it is fed by a continuous tube charged with coke from the top; this opens at the end into a fire-box or basket closed at the bottom by bars, and on these bars are placed a cone which causes an outward distribution of the fuel as it descends from the supply-chamber. Around this supply-chamber there is a concentric casing filled with sand, which retains the heat for many hours after the fire has burnt out, and prevents the heating and cooling from taking place too rapidly. Outside this last casing there is again another casing concentric with it, and between these are three spiral flues. The heat and products from the fire ascend by these flues, and at the top of the casing there are three apertures, by which the products of combustion are delivered in a common up-take which leads to the chimney.

In this way, and by the help of regulating flues, the exterior casing is very equally heated; a sufficient temperature is easily maintained, and this without any risk of overheating the elements. The inner faces of the thermo-elements are in close proximity to this heated casing, although not electrically connected with it. Thus the requisite heat is supplied to the couples, and each row being connected together by binding screws, for convenience, the total number of elements can be arranged row by row, either in one circuit or multiple arc as desired. The electrical current flows as described, and can be employed for any purpose for which it is required.

The stove, simply as a stove, was found capable of producing a tremendous heat, and from an actual trial in testing, before the thermo-elements were added, allowing all the dampers, etc., to be out, and giving it full play, within twenty minutes of lighting the fire such heat was generated that lower parts of the iron furnace melted like wax.

This electrical furnace, this magnopile, gave in actual work an E.M.F. of 96 volts, with a resistance of 11·5 ohms. This resistance

Digitized by Google

need not have been more than 10 ohms, and better results can yet be obtained. The cost was at the rate of about 6d. per 10 hours."

We regret to have to add that beyond the above quotation we have failed to find any hint or suggestion of the slightest value in this book. The author has taken no pains to qualify himself for the task of propounding a new Physical Theory of Electricity; his ideas so far as they are new are certainly untrue, and so far as they may possibly be true, they are by no means new. In fact, the pamphlet furnishes one more instance of a novice rushing in where Sir William Thomson scarcely dares to tread.

THE BIRMINGHAM ELECTRICAL EXHIBITION.

The arrangements for the opening, on August 1st, of the Exhibition of Electrical and Industrial Appliances in Bingley Hall, Birmingham, are rapidly approaching completion. About twenty-six thousand feet of space are at the disposal of the Committee, most of which, practically, will be devoted to electrical appliances. Our readers will remember that the exhibits are grouped in three sections; one will consist of a complete display of electric lighting upon all known systems and combinations, and of all systems of electric transmission of power; the second will embrace dynamos, arc and incandescent lamps, switches, electroliers, and motors; and the third, telegraph and telephonic apparatus, phonographs, electric bells, and all kinds of electric machinery and appliances. All the machinery in motion will be worked by electricity, five powerful engines to work the dynamos being supplied by Messrs. Robey and Son, Ruston and Proctor, and Greenwood and Batley, and the boilers by Messrs. Galloway and Sons.

The lighting of the hall has been entrusted to the leading electric-lighting firms, among them the Anglo-American Brush Company, Elwell Parker, Ernest Scott and Co (Newcastle-on-Tyne), the Planet Electric Light Company, Messrs. Goldston (Middlesbrough), and Shippey Brothers. The motors for driving machinery for the working exhibits will be supplied by Elwell Parker, Messrs. Immisch and Co., Crompton and Co., and Messrs. Laurence, Paris, and Scott.

One of the features of the Exhibition is to be a miniature coal mine, in full operation. Excavations are being made in the basement of the hall, in which a seam of coal will be represented. Lord Shrewsbury has lent all the machinery necessary to coal-getting. A tramway will convey the coal, which will be worked by a staff of miners, to the pit's mouth. The mine will be lighted by electricity, but visitors will be asked to carry a safety-lamp into the workings, and this will greatly add to the air of realism which it is intended to convey. Another novelty will be a telpherage railway, worked by electricity. A wire will be run round the hall, and engine and coaches to carry passengers will be suspended.

The electrical exhibits will be of the utmost value. Birmingham is at the present undecided as to whether it will adopt electricity as an illuminant, and the exhibits have been carefully arranged to show the different systems at their best. Amongst the exhibitors are the Edison and Swan United Electrical Company, who are showing a number of lamps of a very elaborate kind; Messrs. Crompton and Co., who are showing their new improved electrical cranes; the Electric Power Storage Company, who exhibit storage cells; and Woodhouse and Rawson (Limited), who show an assortment of switches and fittings. There are in all about 300 exhibitors, being considerably more than at the Exhibition of 1886.

Permission has been obtained from the property owners in the neighbourhood to run a wire along the roofs of the houses, and at intervals along the route large arc lamps are to be suspended from an arm placed over the shop fronts. Electricity will, moreover, be the illuminant in King Alfred's-place, the town end of Broad-street and Paradise-street, and if permission can be obtained the lighting will be continued to the Town Hall, a considerable distance. Altogether it is hoped that when Lady Randolph Churchill opens the Exhibition on Friday next a very interesting display will have been got together.

ON FREE IONS.*

BY W. OSTWALD AND W. NERNST.

The hypothesis originally propounded by Clausius, that in an electrolitically-conducting liquid a portion of the electrolytic molecules are split up into ions, has, as is well known, recently received a further development at the hands of H. Arrhenius, who has shown how to determine the proportion of the whole quantity of the electrolyte, which under given conditions is split up into ions. A considerable number of quite different methods of investigation have led to results which all agree in indicating that in the case of most neutral salts, as well as of the stronger acids and bases, instead of a small portion only of the electrolyte being split up, as had hitherto been assumed, almost the whole is split up in this way into ions, leaving only a small proportion of molecules existing in a combined state in the solution. The older and comparatively indefinite theory gave a complete and what appeared to be a satisfactory explanation of the phenomena, but the new and definite form appears to involve some contradictions. One of the present authors has shown ("Zeitschrift für physikalische Chemie," Vol. II., p. 271, 1888) that the existence of free ions in an electrostatically-charged electrolyte must be assumed, as the contrary assumption would be in contradiction with the fundamental laws of electricity.

The authors observe, however, that so many attacks have been made upon their method of experiment and from such weighty sources, the experiments in the form described being asserted to be impossible, that they have endeavoured to place their conclusions upon an unassailable experimental basis. It is well known that the electrical charges in motion in case of electrolysis are beyond comparison greater than those which can be obtained electrostatically, and therefore specially delicate apparatus has to be employed in order to observe the electrolytic action of statical electricity. As an exemplification of this the authors point out that, according to their results, in order to obtain a sufficient quantity of electricity from a single discharge of an air condenser to liberate a milligramme of hydrogen the linear dimensions of the condenser would have to be something like a kilometre. However, as they point out, a milligramme of hydrogen would occupy 12 or 13 cubic centimetres, and as a bubble 0·1 millimetre in diameter can be perceived by means of a simple lens, and one 0·01 millimetre in diameter by means of a microscope, the linear dimensions of a condenser necessary to give an observable effect would be measured in decimetres or centimetres. The authors state that the best means known to them for the observation of small quantities of hydrogen, lay in the use of Lippmann's capillary electrometer. The apparatus actually employed in the experiments consisted of a glass tube 30 to 40 centimetres in length, provided with a stop-cock, and terminating in one end in a capillary tube of such dimensions that when filled with mercury the pressure just exceeded that of capillarity, so that mercury began to flow out in drops. The tube was fixed vertically in a holder, and its end was allowed to dip into dilute sulphuric acid. The mercury was then drawn up into the capillary tube by sucking at its upper end, and the acid allowed to take its place. The bounding surface between acid and mercury was then brought, by means of the stop-cock, to a fixed position at about the middle of the capillary tube. A platinium wire melted into the tube gave the means of making electrical connection with the mercury. With this apparatus the following series of experiments was made:—

(1). The large glass globe had its globular surface covered with tin foil and its neck varnished with a solution of shellac in order to make the insulation as good as possible. It was then filled with dilute sulphuric acid, and the contents of the sphere were put into electrical communication with the acid, in the Lippmann electrometer tube previously described, by means of a wet fibre. The sphere was insulated by being placed on a sheet of gutta percha. The positive terminal of a small electrical machine was then connected with the outer coating of the sphere, while the mercury of the capillary electrometer was earth connected. As soon as the electrical machine was set in motion the meniscus of the capillary electrometer moved upwards, and at the same moment gas bubbles were separated and divided the mercury thread at several parts. In this way a positive charge was communicated to the external coating of the sphere and this would attract and bind the negative charge upon the inside, repelling the positive charge; the repelled charge would pass through the wet fibre to the capillary electrometer, and then through the platinum wire in connection with the latter to the earth. The authors observe that a closed circuit is not necessary, the resultant motion of electricity being entirely due to induction. Now, it was shown in the Paper previously quoted that the existence of free ions in an electrically-charged electrolyte followed from Faraday's law, according to which the motion of electricity in electro-

* "Zeitschrift für physikalische Chemie." Vol. III. Abstracted from separate impression communicated by the authors.

lytes only takes place simultaneously with that of the ions. If, then, the motion of electricity due to the inductive action took place by metallic conduction, as some physicists of high standing have asserted might possibly be the case, there would be no reason for the production of hydrogen at the electrode, and the fact that this occurs, shows that the conduction is electrolytic, and therefore that a separation and motion of the ions has taken place. It follows, therefore, that the outer coating of the sphere acquires a positive charge; the negative ions (SO_4) of the sulphuric acid are attracted, while the positive ions (H) are repelled, and travel through the wet fibre to the mercury, where they give up their charges, and appear as ordinary hydrogen, which agrees with the results obtained in the Paper previously referred to. The objection might be made, that the liberation of the hydrogen might possibly be due to electrolytic action taking place through the glass instead of being caused by inductive action. This objection, however, is answered by the fact that the Leyden jar employed kept its charge exceedingly well. Moreover, the authors' conclusion is confirmed by the following experiments:—

(2). While the outer coating of the sphere was in connection with the earth, a charge of positive electricity was communicated to the acid within it by means of a wet fibre. The connection with the electrical machine was then broken and the acid was connected again by a wet fibre with the acid of the capillary electrometer, the mercury being put in connection with the earth. The same phenomenon as before was then observed, namely, the thread of mercury rose in the tube, and bubbles of gas were observed between it and the acid. The explanation of this result is similar to that of the former one; while the acid was being charged positively from the electrical machine, the negative ions lying at the point of contact with the wet thread were neutralised and united with the metal. The positive ions would distribute themselves according to the laws of electrostatics over the surface of the conductor; when the acid was then earth-connected through the capillary electrometer, there was a flow of positive electricity with the hydrogen to the mercury, and the electric charge escaped. The hydrogen remaining in the form of bubbles, and without electrical charge.

(3.) The acid of the capillary electrometer was connected with the earth, and the mercury with a metal plate having sides a few centimetres in length. This plate was then brought near to a second plate charged negatively, whereupon bubbles of hydrogen immediately appeared in the neighbourhood of the meniscus. In this case positive electricity flowed through the earth towards the first plate, and the bubbles of hydrogen observed evidently consisted of the gas accompanying the positive current.

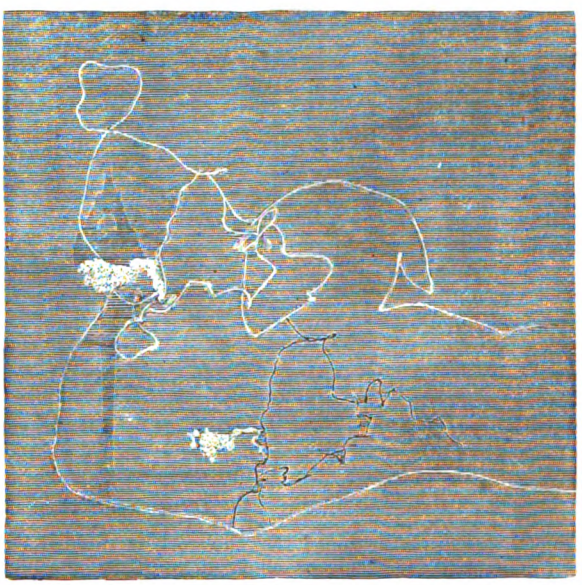
(4.) The upper mercury surface of an ordinary Lippmann capillary electrometer was connected with an insulated metallic sphere, and the latter was then acted upon inductively by the approach and subsequent removal of a rubbed rod of glass or ebonite, and the thread of mercury in the electrometer was seen to move through a perceptible distance in the direction indicated by the previous results. The motion in the capillary electrometer is due, as is known, to the changes in surface tension, and arises from alterations in the difference of potential of the electrical double layer at the bounding surface between the mercury and acid, that is to say, the mercury meniscus becomes polarised through the inductive action. Now polarisation can only arise from material changes in the boundary layer. The motion of electricity in the acid must therefore be of an electrolytic character, that is to say, it must be accompanied by the motion of the ions, so that even in the case of the motion of this extremely small quantity of electricity there is no perceptible sign of metallic conduction.

In order to show that under the given conditions a definite electrolytic action was to be expected, the author then repeated the experiment quantitatively. The capacity of the globe for a charge of short duration was determined by alternately charging and discharging it through a sensitive galvanometer many times in a second, and the throw of the galvanometer was compared with that due to the action of a small fraction of the charging E.M.F. applied directly to the galvanometer circuit. It was found in this way, that the capacity in electro-magnetic measure was $6{\cdot}9 \times 10^{18}$ C.-G.-S. units. In making the experiment the globe was charged to a potential difference of 800 volts which would give it a charge of 8×10^{10} C.-G.-S. units, so that the quantity of electricity due to induction which passed through the capillary electrode was $5{\cdot}5 \times 10^{-7}$. Now a C.-G.-S. unit of electricity liberates 0·014 milligrammes of hydrogen, so that, under the ordinary conditions of temperature and pressure, $0{\cdot}3 \times 10^{-7}$ cubic centimetres of hydrogen would be expected to appear in the capillary tube. As a matter of fact a bubble of hydrogen was obtained of a length about double that of the internal diameter of the capillary tube. Now it was observed that in order ot force the mercury down to the position of the bubble in the capillary tube, the glass tube attached to the latter had to be filled with mercury to the height of 23 centimetres, the capillary tube having been previously filled with air. From this observation, with the aid of Quincke's tables for the surface tension of mercury, the internal radius of the tube at this point was calculated and found to be $3{\cdot}7 \times 10^{-3}$ centimetres. With these data, and assuming the form of the bubble to be a spheroid with principal axes r and $2r$, the volume was found to be $4{\cdot}3 \times 10^{-7}$ cubic centimetres, which, considering the nature of the experiment, may be regarded as in very good agreement with the predicted value. The authors consider themselves justified in concluding from these experimental results that the motion of electricity in electrolytes in obedience to Faraday's law, is due entirely to the motion of material particles, namely, ions, and that in an electrostatically charged electrolyte there must exist a certain proportion of free ions corresponding to the amount of charge. These ions will, as before pointed out, distribute themselves in obedience to the laws of electrostatics over the surface of the conductor. The authors observe that it might possibly be suggested that the ions are set free at the moment of charging, so that a kind of electrolysis takes place within the liquid simultaneously with the flow of electricity. Clausius, however (Poggendorff's *Annalen*, Vol. CI., p. 338, 1857), has pointed out that this is in contradiction with the experimentally observed fact that electrolysis can be produced by the very weakest E.M.F., which would be impossible according to this hypothesis, for then electrolysis could not begin until the electricity had done a definite amount of work.

(To be continued.)

AN EXTRAORDINARY LIGHTNING FLASH.

The accompanying block is taken from a photograph sent us by Mr. A. H. Baird, of Edinburgh, and which was taken about



9 p.m. during the storm of the 6th June last. The flash at the time did not appear to be of the usual zigzag character, but left the impression of a confused whirl, just as is shown in the photograph. At the moment the flash occurred Mr. Baird was outside a window, holding the camera in his hands.

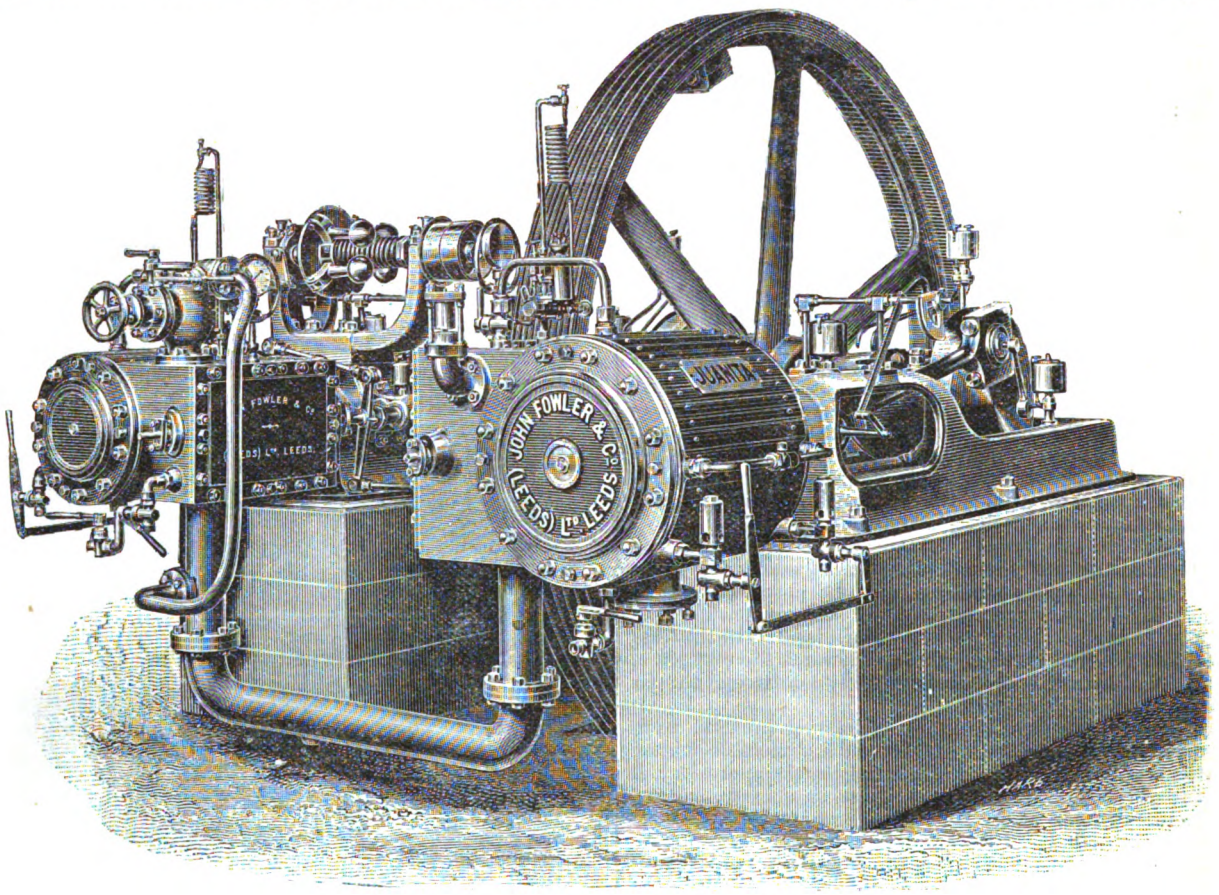
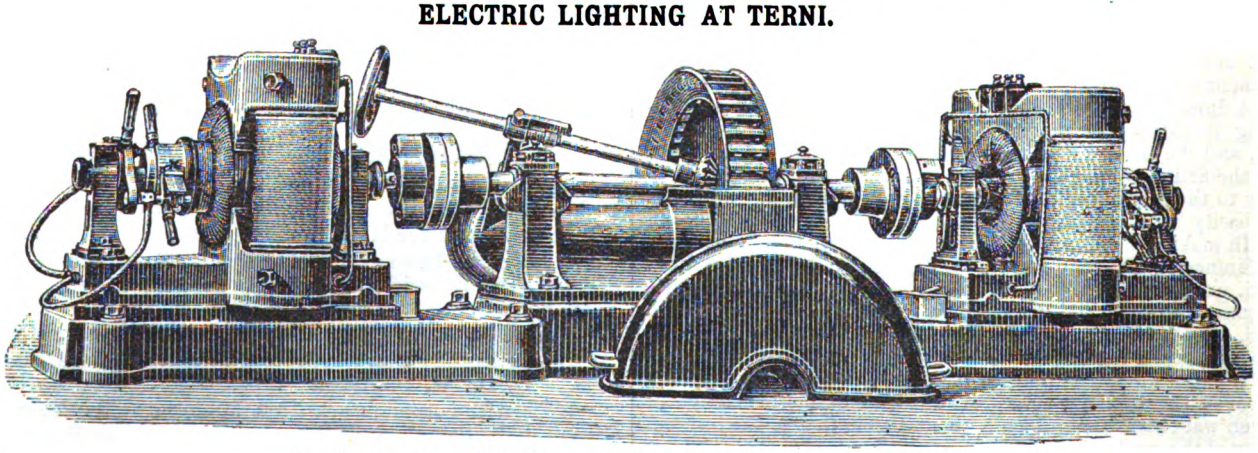
COMPOUND HORIZONTAL ENGINE FOR ELECTRIC LIGHTING.

We illustrate below a compound horizontal engine which has been specially made by Messrs. John Fowler and Co., of Leeds, for Colonel North, to drive the electric light installation at his mansion at Eltham, Kent. The engine is of 25 nominal horse-power. The high-pressure cylinder is 10in. and the low pressure 16in. diameter by 20in. stroke, and the speed is 120 revolutions per minute. Both cylinders are fitted with Hartnell's automatic expansion gear, controlled by one governor, which ensures great steadiness in running. The flywheel is grooved to receive five 1¼in. ropes and is 10ft. in diameter. This engine is specially constructed for long runs, and has drop-sight lubricators to all the bearings and sight-feed lubricators on both steam chests. The cylinders are steam-jacketed throughout, and so proportioned that the work is divided equally between them, and the shocks to which an ordinary high-pressure engine is subject are avoided and great steadiness in work is obtained. To facilitate starting a valve is provided for admitting steam from the boiler to the low-pressure steam chest, which is closed automatically. By this means more than the ordinary power of the engine is available if wanted for a short time. The motion work is of best hammered scrap-iron, polished, and all the wearing parts are case-hardened. The crank-shaft is of hammered steel, with balanced cast-iron crank discs; the cank pins are of steel, forced into place by hydraulic pressure. The bed-plates are of cast iron, and of the deep box pattern, ribbed inside and flanged to provide large surfaces for contact with the foundations. The main bearings and slide-bars are formed in the same castings with the bedplates. The slide-bars are cylindrical and bored in line with the cylinders. The main bearings are fitted with large adjustable brasses of best gunmetal. Messrs. Fowler, we may add, were the first to apply the compound system to semi-fixed and fixed engines, and the success which has attended its application is shown by the largely increasing demand for compound engines.



Compound Horizontal Engine by Fowler and Co., of Leeds.

ELECTRIC LIGHTING AT TERNI.



The Combined Arc Light Dynamos and Turbine at the Terni Steel Works.

The above illustration, which we take from the *Centralblatt*, shows the nineteenth and twentieth dynamo and tenth turbine which have just been put down in the installation at the Terni Steel Works. The machines have been built by the Esslingen Maschinenfabrik, and, as will be seen, each turbine drives two dynamos. The total number of lamps now in use at these works is 160 arcs and about 1,000 incandescents. Power is obtained from the River Velino, 8,000 horse-power being available.

The illustration shows two 10-arc lighters with a 20 horse-power turbine.

WOODHOUSE AND RAWSON UNITED (LIMITED).

An important amalgamation of electrical companies takes place this week in which are concerned the four Woodhouse and Rawson Companies and Messrs. Charles L. Baker, of Manchester. It may be recollected that Woodhouse and Rawson, who were one of the earliest firms to start in the electrical engineering business some time ago, formed different portions of their business into limited companies, their reason being, as we are informed, that in order to extend the business several partners were taken into these branches, which were then turned into limited companies to avoid unlimited liability and to define the rights of the several partners. Woodhouse and Rawson (Limited) was formed shortly after the well-known action with regard to incandescent lamps, and as the business had been much disturbed by the result of this action the directors paid nothing for goodwill or patents, except Founders' Shares, which entitled the holders to four-fifths of the profits after 10 per cent. had been paid on the Ordinary Shares. Now that the effects of the action have been got over and the subsidiary companies are also in a paying position the amalgamation of the whole of the interests has been effected. The combination obtains the services of Mr. Baker, who will take charge of the manufacturing department, and his well-established business is also absorbed. The combination has the advantage of a strong and practical Board, and from what we hear the Company seems to have met with considerable response from the public. No doubt the actual depositing by Woodhouse and Rawson (Limited) of £75,000, profits of the last year, which £75,000 is practically what the Founders' Shares of Woodhouse and Rawson (Limited) will be entitled to, has proved a great attraction, showing the confidence that the original proprietors had in the future of the new concern. On the whole we congratulate those interested in the business, and think that if the new company is carried on with the same energy as the old, there ought to be very good results to the new shareholders.

AMERICAN NOTES.

(from our own correspondent.)

New York, *July* 13, 1889.

There is no need to remind your readers of the fact that the Brush Electric Company is a pioneer in its field, and that with its name are associated some of the earliest and most striking triumphs in arc lighting development. Mr. Brush's originality has attracted notice abroad as well as at home, and the apparatus of the company was practically the first upon which large and enduring and successful local companies were established. As long ago as 1875, Mr. Brush's attention was occupied with the problems involved in electric lighting, and though of late years he has not been so prominently before the public, he has still been quietly and actively at work on one thing or another. The recent decision in our Courts with regard to Mr. Brush's early work in thestorage battery field, did much to fix attenattention on him again, and now he comes forward with another bid for public favour in the shape of a well-developed alternating current system, bringing his work and invention fully abreast of the latest theory and practice of the time. This alternating current apparatus, in the perfection of which Mr. Brush had the valuable assistance of Mr. Gustav Pfannkuche, the well known electrical engineer, is already being put upon the market, and thus, owing to the prestige which the Brush Company enjoys, together with its numerous footholds and the claims which the apparatus makes for superior economy and efficiency, it seems likely that it will soon occupy a prominent position. One of the most characteristic features of the system is that the alternating generator has a stationary armature which contains no magnetic material whatever, and which is so constructed that any individual coil may be cut out, removed, and put back again without stopping the machine. The field magnets revolve, being carried by the shaft. The machine generates a current of 2,000 volts. The converter used is not unlike the well-known Brush armature used in arc lighting. The core consists of a polygonal ring made of insulated iron wire of the best quality, so wound as to leave several concentric air spaces in the core. In the smaller sizes the core is built up of thin perforated iron plates. In both cases the iron is so divided, that the efficiency of the converter is little less with half load than with full load. On each side of the core is wound a single layer of heavy copper wire. Four or five single layers of coils carried by each half of the core are joined in series, and the two groups borne by the two halves of the core are joined in multiple, the whole constituting a secondary core. Most of the converters are wound for a secondary current potential of about 100 volts, but they may be instantly connected so as to give 50 volts. They are made in all sizes, ranging from 2 up to 250 lamps. Ventilation has been specially provided for in this converter, the insulation resistance is remarkably high, and it is said to be virtually impossible to so overload the primary so as to break down the insulation and short-circuit into the secondary. With regard to the performance of the alternating generator, a card is published which shows that the fall of the potential in the machine from no load to full load is less than 10 per cent. This result is reached without compound winding or artificial regulation of any kind, a result which is said not to have been approached by any alternating machine with iron core armatures. All the regulation needed is applied at the exciter, which is a small Brush dynamo of the old familiar type, accompanied by a rheostat worked by hand, or automatically, placed in shunt-circuit around the exciters' field magnets. It will have been noticed that the potential in this new alternating system, which represents the deliberate judgment of a corporation that is conservative as well as progressive is no less than 2,000 volts. I should not be surprised if some systems which have hitherto been contented with the lower voltage, say in the neighbourhood of 1,200, bring their standard up to the higher point thus fixed, in spite of the adverse clamour on the subject.

In view of all the agitation on the danger from electricity and the claims of sensational articles in the newspapers, it is a relief to find, from a table just published by Dr. Wheeler, of the Subway Board, that last year while there were no fewer than 1,258 deaths from accidents in this city, only five of these were due to electric shock, and if the investigations were carried a little bit further it would be found that even in these cases the "accident" was more a display of absolute, downright carelessness than anything else. Looking over the table, for example, one finds that although these wonderfully-dangerous electric wires run all over the city in every direction, and on some streets may literally be counted by hundreds, there were ten times as many deaths from the fall of heavy bodies, six times as many from falls through elevator shafts, six times as many at fires, nearly forty times as many from drowning, nearly seven times as many from gas, and just about as many from food. The table shows, in fact, that there were almost as many deaths from being "sat upon by father" as there were from all the electric light wires and plants in the whole of this great metropolis.

Such being the showing, one need not wonder that the various points involved in execution by electricity again come up for review, and that people should more and more incline to the opinion that it would be well not to employ the current as a means of capital punishment until more is known about it and its effects. As I wrote you recently, the judge before whom the appeal of the murderer Kemmler was heard, referred the matter for the taking of testimony to prove or upset the contention that electrical punishment was "cruel and unusual"; and during the present week the referee has been sitting in this city, hearing the evidence of a number of experts, including Mr. Harold P. Brown. The drift of the evidence was that although a good deal had been ascertained with regard to the effect of the current on animals, the results on human beings had not yet, so to speak, come within the category of *res adjudicata*.

The Thomson-Houston Company is feeling greatly elated over its recent good luck in securing the contract for the operation of the West End Street Railway Company's system in Boston by electricity. The arrangement is that the West End Company will purchase the poles and set them, and furnish current for propelling the cars, while the Thomson-Houston will do the entire electrical construction and supply motor trucks. The West End Company has already purchased a large building and intends to convert it into an immense power station of eight or ten thousand horse power capacity for supplying current all over its vast system. Of course, it is not to be supposed that

Digitized by Google

the whole of this work will be done at once, but even if it be done in sections, the work of equipping one hundred cars at a time, and putting them into operation will involve no mean electrical engineering, especially in Boston, where the grades are often sharp, and where the crookedness of the streets is equal to that characteristic of so many of the thoroughfares in London.

An appointment just made by President Harrison is of some little interest. I refer to the appointment of Prof. T. C. Mendenhall, of Terre Haute, Ind., as superintendent of the Coast and Geodetic Survey. Prof. Mendenhall, who is an Ohio man, was Professor of Physics and Mechanics in Ohio University from 1873 to 1878. He then went to Japan as Professor of Physics in the Imperial University at Tokio. In 1881 he returned to the United States, and to Ohio University. In 1882 he organised the Ohio State weather bureau service, and devised a system of weather signals for display on railroad trains. He became associated with the United States signal service in 1884, and established stations in the United States for the systematic observation of earthquake phenomena. In 1886 he left the Government service to accept the presidency of the Rose Polytechnic Institute, of Terre Haute, Ind., a position which he still holds. At Terre Haute, assisted by Prof. Gray, whose brother is so well known in scientific work in England, he has done much to develope electrical studies, and has established a special course in electricity. Prof. Mendenhall is the author of a handy little book, entitled "A Century of Electricity," and he is also responsible for the electrical portions of the superb new dictionary of the English language now being published by the *Century* Company of this city. It will be seen, therefore, that President Harrison has made a good choice, and has recognised the claims of scientific attainment and experience.

The use of the electric motor for stationary-power purposes is rapidly becoming popular, and the system is already familiar to large classes of power users, who but a few years ago had as much idea of driving their machinery by moonbeams as by the electric current. The newspapers have done good educational work in this respect, and have themselves been remarkably prompt in appreciating the good points of the motor, and in adopting it. There are now large numbers of printing offices in this country where electricity is the only power employed. Even where it is not the intention to adopt electric power permanently, it would be an excellent resource in times of emergency. An episode that occurred recently at Washington illustrates this point. The *Star*, of that city, a large evening paper, suffered from the invasion of the Potomac floods, and had its printing office disabled by the falling in of the walls upon the engines. In such a pinch, and not desiring to be dependent upon the charity of neighbours in the matter of making its issues, the *Star* resorted to electric motors. The arrangements were readily carried out by the local electric light company. C. and C. motors were ordered by telegraph from New York, and in a few brief hours the motors were set up and in operation, giving the most satisfactory results. It is hard to think of any other way in which the newspaper could have tided over the difficulty, and anybody can see that such an accident as this not only makes a warm and powerful friend for the electric motor, but will do much of itself to satisfy printers that electricity is what they need.

An interesting controversy has arisen between the Western Union Company and the Postmaster-General with regard to the rates to be paid by the Government for telegraphic service. Ever since the time that the law regulating the matter was passed in 1866 a rate of one cent per word for dispatches of 20 words has been charged, and one cent for every additional word, with 10 per cent. added for distances over each one thousand miles. By dint of long usage this rate had become accepted as the standard, and the Western Union Company had taken it for granted that there would be no attempt to disturb it. The Postmaster-General, however, in filling out blanks for the fiscal year has made them out at the rate of one mill per word instead of the customary one cent, so that the company would get only one-tenth of what it received before. It can be readily understood that in the course of a year the Government business amounts to a tolerably large sum, and under the new conditions the Western Union Company would prefer to let it alone rather than do it at a loss. It seems, however, that the Postmaster-General is well within his technical rights as conferred upon him by the statute; hence, he is practically master of the situation. The Western Union Company are now discussing the matter with the Government, and hope to secure some modification of the new terms. Nobody supposes for a minute that the rate of one mill per word is anything like adequate compensation, and in some quarters there is a disposition to regard the action of the Government as significant of other movements in the same direction. This, however, seems hardly probable, as there is no vigorous sentiment in the country at the present time in favour of Government telegraphs.

In a previous letter I mentioned the movement toward consolidating the various Westinghouse electrical interests. It is now understood that the plan has been carried through, and that the stockholders of the Westinghouse Electric Company, at a meeting held at Pittsburgh on July 11, decided to reorganise under the name of the Westinghouse Electric and Manufacturing Company, employing for the purpose a charter of the Chartiers Improvement Company, granted as far back as 1871, conferring powers and privileges that cannot now be secured under existing legislation. Now that the new incorporation has been effected all the various Westinghouse interests will be consolidated into one, each constituting a department of the new business. It is stated that the company is now employing 2,000 men.

CORRESPONDENCE.

LIGHTNING PHOTOGRAPHY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Of the many problems that await development and explanation, not the least interesting are those relating to lightning, and of several such we may mention the peculiar form of electrical display termed "ball lightning," and the curious "branch-markings" sometimes observed upon the bodies of persons said to have been struck by a flash.

These and many other phenomena, although unexplainable, are nevertheless accepted by scientists as verities. The views of scientists are not, however, always broad, for when we come to the reported phenomenon of "lightning photography," *i.e.*, the reproduction by lightning of the image or resemblance of some adjacent object upon the body of a person said to have been struck, the unexplainable is derided and thrown amongst the fictions.

It is this last-mentioned effect that I select for present remark.

Of several reported instances of "lightning photography" I quote the following:—

"September, 1825.—The brig 'Buon Servo,' in the Bay of Armiro was struck by lightning, and a sailor sitting at the foot of the mast was killed. Marks were found on his back, including the impression of a horseshoe, perfectly distinct, and of the same size as the one that was fixed to the mast."

"At Zante, the number 44, in metal, was attached to the fixed rigging between the mast and the cot of one of the sailors. The mast was struck and the sailor killed. On his left breast the number 44, well formed and perfectly identical with that on the rigging, was found marked. The sailors agreed that the number did not exist on the body before the man was struck."

"M. José Maria Don, of Havannah, states that in 1828, in the province of Candelaria, Cuba, a man was struck by lightning, and on his neck was found the image '*d'un fer à cheval que avait été cloué à peu de distance contre une fenêtre.*'"

This question of "lightning photography" was raised by myself during the discussion which followed the reading of Prof. Oliver Lodge's Paper at a recent meeting of the Institution of Electrical Engineers; and it was then demonstrated, in connection with my remarks, that a variation in electrical condition was always attended by a radiation of force. The sugges

Digitized by Google

tion was also made that possibly the similar but vastly greater force radiated from substances under stress by lightning would be capable of effecting an electro-chemical change, such as was apparently needed in order to an explanation of "lightning photography," and moreover that where, in the case of flat surfaces, the lines of force would be parallel, there should be no difficulty in apprehending the possible formation of a mark bearing some resemblance to the object by which that force was evolved.

Of course unsupported theory is of small value, but it happens that a question then present to my mind has been experimentally asked and answered, and it is the answer that I wish now to give.

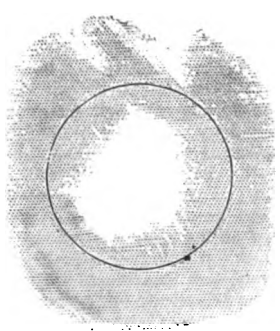
The question was: "If under such conditions as those just mentioned it be possible for lightning to effect such markings as those quoted above, then surely this same remarkable radiated force should have the power of also electro-chemically reducing potassium in saturated paper?"

In testing this question of "radio-chemical" effect a Ruhmkorff was used, the ends of the secondary coil being respectively connected to two flat metal surfaces. The two opposing surfaces were brought into juxtaposition, with sufficient interval between them to prevent sparking.

With this arrangement the radiatory and sonorous effects exhibited during the discussion already referred to were apparent.

A piece of clean blotting paper, moistened with potassium solution, was then laid upon one surface, and colouration by electro-chemical reduction immediately set in, increasing in intensity as the minutes went on, the raised parts of the uneven paper being the more quickly and darkly coloured.

The prepared paper could be laid upon either plate with a like result, as also if, insulated from both plates, the paper was simply suspended between them.



A piece of prepared paper, laid upon the centre of a piece of ¼in. plate glass, with one metal plate suspended over it, the other being abolished, was also coloured, although the period of exposure that was required for a given tint was very much in excess of that needed in the experiments previously mentioned.

Many experiments were tried, in which, whilst a piece of prepared paper lay upon one plate, a conducting substance of some particular shape was suspended over it, and it became evident that although outer edges and corners produced the more marked effects, the form of the inciting object would be distinctly discernable upon the paper. I submit herewith a few examples:—

No. 1. Flat surface, the size of a farthing; time of exposure three minutes; distance between it and opposing plate one and a-half inch.

No. 2. A circle; time, five minutes; distance, two inches.

No. 3. A circle; time, five minutes; distance, two inches.

No. 4. A circle; time, four minutes; distance, two and a-half inches.

No. 5. A circle; time, 10 minutes (very low power used in this case); distance two inches. (*See* Figure.)

This last is a very fine and beautiful specimen of form reproduction. Unfortunately some other good samples have faded too much to be of value. Example 5 presents a very uneven colouration, the unevenness being due to the difficulty in keeping the paper free from puckers.

To what then does this fact of chemical reduction by so-called induction bring us? I think it suggests that if with such comparatively low power we are able to accomplish so much, may we not reasonably believe that the sudden development of incalculable energy usually accompanying lightning will be well equal to the task of driving home with fearful intensity its radiated forces.

I think it may be claimed that, though all is not proved that may be desirable, we have, nevertheless, here recorded a feature which has hitherto apparently escaped notice, and which at the least should lift the question of "lightning photography" above the level of unscientific ridicule.—Yours, &c.,

ALEX. J. S. ADAMS.

A PECULIAR LIGHTNING SHOCK.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: An instance of a severe shock at the moment of a flash of lightning, and due apparently to induction, occurred here yesterday. The man injured was screwing up a nut securing a dynamo to its wooden foundation. The dynamo had no belt on nor its brushes down. It is in a low wooden shed, with a portable engine about five yards off. A pair of double rubber-covered well insulated wires are laid temporarily across the roof of an adjacent building for about 12 yards, and terminate in an arc lamp on the first floor. There is a telephone post near, 10 wires run nearly parallel and about 30 run across the electric light wires, about four yards above them. The lightning was thought to have struck one of the buildings near. No damage has been traced anywhere.—Yours, &c., W. H.

7,526. ALCOCK and GALOPIN. Electric arc lamp. (Price 8d.)

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The 34th half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held on Thursday, July 18th, 1889, at Winchester House, 50, Old Broad-street, London, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. George Draper) read the notice convening the meeting and the minutes of the thirty-third half-yearly ordinary general meeting held on January 24th, 1889.

The CHAIRMAN, having signed the minutes, and the report being taken as read, said: Gentlemen, it is a very full and instructive report, and I hope it will be to the shareholders a very satisfactory report. However, before moving its adoption I will, as I have always done on previous occasions, go over in detail some of the more important points which have occurred during the last six months, so that those who have read the report will more fully understand the results that are shown. The revenue account for the half-year ended March, 1889, shows a total amount from messages of £352,791, as compared with £324,144 in the corresponding half of 1883, being an increase of £28,647. About two-thirds of this increase arises from our South African traffic which has been favourably affected by the political disturbances at Zanzibar. Such disturbances where Governments are so actively engaged generally increase materially the telegraph traffic for a time. The very great activity which has been going on in South Africa on account of the gold mining operations there has also materially increased our receipts. I hope that it will settle down finally into a very satisfactory and permanent business. We are very sanguine that the trade established by those mining operations will, even in ordinary times, be a satisfactory one, and also a growing one, thereby increasing our traffic. Holding these views we have, in concert with the Eastern and South African Company, organised a complete system of telegraphy as an alternative system from the Cape to Europe by the West Coast. This growth of traffic has enabled the South African Company (the greater part of whose capital, as I believe you all understand, is held by the Eastern Company) to pay a largely increased bonus. The shares of the Eastern and South African Company being all but entirely held by the Eastern Company our revenue account shows that we have received as dividend from that Company £79,650, against £31,000 in the corresponding half of the previous year. This £79,650 includes an exceptionally large bonus from the South African Company for the whole year.

I am pleased also to remark that our Egyptian traffic, which has been steadily declining for some years past, shows an increase in the last six months over the same period of 1888, and so, if this small war that is going on now in Egypt continues, I think, when I have the pleasure of addressing you again, I shall be able to show you that war certainly does increase our traffic. I look for a still further increase in our Egyptian business.

One class of traffic alone, namely, the Indian traffic, shows a substantial decrease. This falling off, which in the past half year amounted to £5,550, is engaging our serious attention, but it is satisfactory to know that the decrease in the Indian traffic is more than counterbalanced by the growth of traffic in other directions. Our Black Sea dividend is the same as last time, and our investment in the Direct Spanish Company has given us £184 less than in 1888, that Company having paid a smaller dividend. Transfer fees show an increase of £25, and interest on money at our temporary disposal an increase of £1,095. To sum up, our gross revenue from all sources for the half-year was £435,932, as compared with £359,706 in the same half of 1888, being an increase of £76,226. The total working expenses for the half-year amounted to £92,448, against £87,134, or an increase of £5,314.

The details of increase and decrease are as follows:—General expenses in London were £7,988, against £8,333, or a decrease of £345. The working expenses at the stations were £68,545, against £62,786, being an increase of £5,759. As explained at the last general meeting this is in a great measure due to the increase in the number of our foreign staff, owing to the opening of the triplicate cable from Porthcurnow, Lisbon, Gibraltar, and Malta, and the extension to Zante on which the duplex system is worked, also to the opening of the new station at Cadiz, we having put that place in telegraphic communication with Villa-Real and Gibraltar. It has also been necessary to augment our staff at our other stations to enable us to carry with accuracy and despatch the additional number of messages. As compared with March last year the total increase in the number of our staff at our stations is 41. The increase in our travelling expenses was £750, rent, fuel, and light, £143, and stationery and printing £952, these increases being accounted for by the reasons just given. The other principal items of increase are furniture and fittings, £1,601, and repairs to stations £834. To meet the requirements of the traffic we have found it necessary to add to the accommodation of several of our stations, more particularly in London and at our training school at Porthcurnow, also at Carcavellos, Malta, Alexandria, Suez, Syra, &c. On the other hand, there is a decrease of £1,132 under the heading of maintenance and renewals of electrical instruments and appliances. £1,000 of the total increase in the working expenses is explained by our having carried £5,000 to the general ships' reserve fund, against £4,000 in the corresponding period of 1888. The expense of the issue and the stamp duty on the new capital, £817, also appear in our revenue account this half-year. Repairs to cables amounted to £48,655, against £38,412, or an increase of £10,253. On reference to abstract "C" in the report, full details of the work performed by our ships will be found. It will also be found that the expenses of five ships are included this half-year against four in the same period of 1888, the steamship "Amber," built to replace the "Volta," having been busily employed during the six months under review. The cost of 203 knots of cables used on repairs and renewals (the greater portion of which was used in the extensive repairs to our No. 1 Aden-Bombay cable) is also included. The total increase in our revenue has enabled us to meet the additional expenses incurred during the half-year, and we are going to pay an extra ½ per cent. bonus on the Ordinary shares, including the 20,000 additional shares issued to enable us to take up a like number of Ordinary shares of the Eastern and South African Company.

We have placed also £118,000 to the general reserve fund, against £75,000 last year. The reserve fund with interest received on investments during the half year, the premium on the issue of new shares, the profit on the sale of Direct Spanish Debentures, and the contribution from revenue account of £118,000 for the year ended 31st March, 1889, now amounts to just over half a million sterling. When I mention to you further that as you will see in your accounts, we have out of reserve and revenue spent £782,383. I think I need not make any other remarks to prove to you that our position is a most satisfactory one. Our object is to keep down the capital as much as possible; at the same time to maintain such an efficient system as will command the support of the public, and lead to still further development of the telegraph system.

I have now I think given you a carefully prepared statement of everything that has occurred during the last year. It has been our wish that the shareholders should know everything that we are doing when we have completed the work, and having informed them thoroughly of what we have done we expect from them approval of our work when we can show that it has been satisfactorily done. That brings me to make a few general remarks, and they apply more particularly to the work which we have just completed. I think when I had the pleasure of addressing you last—and it will be in the recollection of many persons—I said we were engaged in a very great and important work—that was, in laying and completing a system of submarine telegraphy round Africa by the West Coast, having already done so by the East Coast. That work we have just completed, and I am glad to say that in the completion of that work we have probably done the biggest and most important work yet done in submarine telegraphy. I may tell you that to complete the surrounding of this great African territory—the country, as many people think, of the future—no less than 17,201 miles of submarine cable have been laid, so you will see we have, at all events, done our part in enabling those who have enterprise to go on and develope the great material wealth of that country. It could not have been done excepting by organisation. We saw in early days that unless something more was done by the West Coast the two or three existing companies could do no good whatever. We also felt that the traffic to the Cape was such that it was important for us—in fact it became a necessity either to duplicate our system by the East Coast, or to lay an alternative line to the West Coast. We found that the laying of an alternative line meant first, security; and secondly, it enabled us to largely increase our telegraphing power, and to open up countries which had not been touched before by the submarine telegraph system. Two or three companies were engaged in that work, we having succeeded in getting them to take very much the same view as we ourselves held. When I last addressed you I asked you to help us by subscribing £200,000 to enable us to take up a like amount of South African Company's shares, and I may add that it has been a very profitable investment indeed; and when I tell you that England, Portugal, France, Spain, the Cape of Good Hope, and Natal are all more or less directly interested in, and have given support to this great enterprise, I think you will see that it has been done under such auspices as should secure permanency to it in the future. More than that, it has given what we have always desired should be given to our system of telegraphy—it has given an international character to it, because all the nations in Europe—in fact, all the civilised nations of the world—recognise now that it would be impossible to live without our submarine system, which brings them immediately into communication with one another. I think that that is a most important point to draw your notice to to-day.

In reading my first remarks I referred to the Indian traffic going down. It is a remarkable fact that during the last fifteen years, while we have, I may say, increased the volume of our traffic by 300 per cent. we have not increased our income by more than 100 per cent. That shows you that we have very clever people to contend with. I do not blame the merchants for codifying, but they have got it to such a state of perfection that even with the increase of trade—the large increase of trade—they are able to conduct their telegraphic correspondence in such a form as largely to reduce the words employed in each telegram. I confess to you that if I were a merchant I should do the very same thing; but I want to say to these merchants that they must take care not to put the screw on too much. There is some talk about the next conference moving to reduce the rates. We cannot reduce the rates unless we can increase our traffic and our income. We shall take very good care of our shareholders in that direction. What we desire is not large dividends, but certain dividends and the dividend we are declaring to-day I think must be

Digitized by Google

generally accepted as a fair, satisfactory, and a good dividend. That will be the object we have in view.

Notwithstanding what I call the very encouraging prospects and the solid position of this Company, we have a deal of work before us yet. Some of our cables are getting old. We want to increase our capital as little as possible, but we must be provided with new cables to take the place of old ones when they die out. We are looking for a very large increase in our Australian traffic, and very probably we may make a reduction in the rates; but we shall take care, before we make any alteration in our Indian tariffs, to see our way very clearly. We have a cable from Aden to Bombay which requires very special attention, and if the traffic increases as we expect, and as it is doing, with Australia and other parts, we shall require to put down another cable to give us perfect security and safety, not only between Aden and Bombay, but Marseilles and Egypt. I merely foreshadow these things to show you that while we are earning very large sums of money we have very important work to do to maintain that income; but it will be our mission, and our warmest and most earnest interest, while we are adding to the value of your property, and not materially increasing our capital, to maintain the same satisfactory dividend as we have the pleasure and honour of proposing to-day. With these remarks I beg to move:—

"*That the printed report and accounts of the Directors, to the 31st March, 1889, submitted to this meeting, be and the same are hereby received and adopted; that a dividend on the Preference shares of the Company to 30th June, 1889, at the rate of 6 per cent. per annum, be paid, less income-tax; and that, in accordance with the Directors' recommendation, a dividend be and is now declared of 2s. 6d. per share, with a bonus of 3s. per share, both free of income-tax, on the Ordinary shares of the Company,, making with previous payments by way of dividend on account, a total payment of 6½ per cent. on those shares for the year ended 31st March, 1889.*"

The MARQUIS of TWEEDDALE: I beg to second the motion.

The CHAIRMAN: If any gentleman desires to put any question I shall be very happy to answer it before I put the motion.

Mr. FIELD: I should like to ask a question of Sir James Anderson—whether he would state what is the length of life of a cable?

The CHAIRMAN: I wish you were able to tell me.

Mr. FIELD: I put this question because it was the creation of Preference stock of £700,000 to duplicate the Bombay line that gave opposition. If we are to face an expenditure of anything like £700,000 again to triplicate the line it would be a very serious consideration. You foreshadowed that the day would come when it must be done. Is it contemplated to pay the cost out of revenue, or would there be a creation of capital for the purpose?

Captain GOODSALL: You mentioned that 203 knots of cable have been used in repairs. Is that old or new cable?

The CHAIRMAN: We never think it wise to put new wine into old bottles. A ship always carries a certain amount of new cable. If the cable that we pick up is in fit condition we bring it home, examine it, and recoat it, and if it is cable that we can use we re-lay it.

Captain GOODSALL: Then it is laid as new cable and charged as new cable. You say it is re-coated and relaid, is it charged to the Company then as new cable?

The CHAIRMAN: Have you any other questions?

Captain GOODSALL: Kindly answer that question first. You said the cable you bring home is re-coated and relaid, if thought advisable to do so. It cannot be new cable and be relaid.

The CHAIRMAN: Will you finish your speech and then I will answer you? There are other gentlemen waiting to address the meeting.

Captain GOODSALL: Will you tell me the number of months for which this £1,512 for the expense of the "Chiltern" in dock in London was for? You say in the revenue account "expense of the 'Chiltern' in dock in London." When did the "Chiltern" leave London, or has she left London?

The CHAIRMAN: Will you please go on?

Captain GOODSALL: You will answer these questions?

The CHAIRMAN: Oh yes.

Captain GOODSALL: At your last meeting I drew attention to the exorbitant expense for advertising. I see it is reduced by £100. I think it may be reduced a great deal more. You have no great competition. You are joined with most of the cable Companies. Why should you spend so much money in advertising? It is not necessary. There is, too, only one paper which you advertise in, and I think these expenses might be reduced considerably.

Mr. HURST: I have been a shareholder for many years in this Company—I think almost from its commencement—and I have watched its progress attentively and carefully, and I must say that all that I have seen, and all that I remember respecting the management of this Company has been in the highest degree satisfactory. You have gone through the report and accounts, and we have also had a good and excellent explanation from the Chairman of all the various items of the accounts. They all seem to tell extremely favourably, I think, and there is one point I should very much congratulate the Company upon, that is the care taken by the Directors to put our system on a solid and firm foundation. This is clearly proved if you look at it from the point of view of the amount of the reserve fund. You find that to the general reserve fund (and there are other reserves) no less than £118,000 is put for the past year. Well, this gives a degree of security that must be satisfactory to everyone. There is another circumstance very favourable to the Company, and which must give us great satisfaction. It is this—that when we were not receiving the dividend which we are now receiving, that is, when the Company was in a different state from what it is now, the Chairman and Directors did not buoy us up with any fallacious statements. The statements were clear, and when we received only 4 per cent. they did not calculate and hold out any expectations that we should receive the amount of dividend that we are now receiving. The bonus is also very satisfactory. The growth of the Company is one of the most marvellous things of the world. Our system goes to every quarter of the globe, and its growth every year is one of the most marvellous things of the present age. I think we may express ourselves extremely satisfied with the way the thing is worked, and I have no doubt that we shall still year after year have as good a dividend and as good prospects before us as we have at present. The Company seems on so firm and so solid a foundation, that I think there is no doubt whatever of its continued success and advancement.

Mr. MILLIGAN: I had wished to ask one question on behalf of friends in India and Ceylon—whether there was any possibility or likelihood of a reduction of the tariffs there? Your remarks are eminently satisfactory and encouraging on every other subject, though they are rather discouraging on that one. I should like you, if you were able, to give some hope of a reduction of these tariffs ere long, because I am told that the present rates are prohibitive, and that, therefore, the people resident in the East adopt the codes to which you referred in order to reduce the expense of telegraphing messages. I would only quote the great example of the Post Office to show that a reduction in the tariffs may result in a great increase of revenue, and I think it would be the same in our case if you were able to reduce your charges to Ceylon and the East. I made the suggestion before knowing how well the interests of both the shareholders and the public are considered. I would take the opportunity of alluding to the invitation you make to send you proxies. It is a course that may be very desirable where there is as sometimes happens a conflict of opinion between the shareholders and Directors. That, however, is not the case here, and it is not likely to be the case, and therefore the issue of proxies seems to me unnecessary. Our meetings are so very harmonious that I think it would be found advisable to stop the issue of proxies.

Dr. WALLER: I merely rise to say that I think it will be much better for us to reserve any further observations until you answer the remarks that are now before you.

The CHAIRMAN: The first question, I think, was as to the life of a cable. We at one time thought that ten years would be the life of a cable. I have heard people assert—engineers and practical men—that a cable may live ninety years. We have repaired cables that have been down for fifteen, sixteen, or twenty years, and they seemed to be in very good condition. A great deal depends on where the cable is lying. If it is lying on a mud bank or gravel bank, where there is little friction, and where there is no suspension of any kind, the chances are that cables live for a very long time. If they are in a current or in any position where there is a great deal of friction, the life of a cable is materially shortened. It is just one of the features connected with submarine telegraphy that we cannot tell what the life of a cable is; but we know the value of telegraphic communications, and with an increased traffic we are bound to be prepared in the event of a cable giving out. We must then have duplicate, and in many cases triplicate, lines. The real purpose of telegraphy, to be beneficial, is that it must be continuous. Trade is being conducted almost entirely by telegraphy. The operation begins with a telegram and is closed with a telegram, and therefore we must have no interruptions, because if we had interruptions confidence would cease.

The next question is from Captan Goodsall, to whom I referred at our last meeting. Captain Goodsall has put a question which I think, if he had been watching and observing, he might have satisfied himself about without coming here to make the inquiry to-day, as to where the "Chiltern" is. I should have referred to the "Chiltern" in my opening speech. The "Chiltern" has been employed in the last few days in completing a contract with the French Government for laying a cable from Perim to Obock. We have, in the last two days, exchanged telegraphic congratulations on the successful laying of that cable, and for that contract we shall receive something like £1,500 per annum. It is a small capital; so you see the "Chiltern" has been very usefully and satisfactorily employed. She is now about to relieve the ship bearing my name, and that ship will return to London.

As to "re-serving" for cables, that is another question, which, as a matter of detail, belongs to the experts of the Company; but, as I said, when we pick up a cable, if it is good enough to re-lay it, we do so; but we do not charge anything but the cost of re-coating. We do not put it down as new cable. We utilise these cables in short lengths and in shallow water, and where we find they come in at times very usefully.

As to the question about advertising, if you look at other companies, and compare our Company, which is a company of six millions, you will find that our advertising expenses for the six months have been £450, I think you will admit that it is necessary to keep ourselves before the public in a certain way, and that is a very small sum. (Hear, hear.) I think many of the companies you see advertising spend three times that amount. However, the point Captain Goodsall is aiming at is this, and I stated it fully before, and there is not much use in my repeating it again—£130 of that amount is for *The Electrician*. *The Electrician* belongs to myself and a few other gentlemen who are interested in electricity. I told you last time that we had not started that paper for the purpose of getting money out of it. We have never taken a shilling profit out of it. We pay a high price to the men who write the scientific articles, which are of a very high class, and we send *The Electrician* to every station, so that our young men, who are to be the men of the future in electricity, may know everything that is going on about it. There is nothing I am more proud of than the way in which *The Electrician* is conducted. It is a high-class paper. We have the very best scientific men writing for it, and all that is done for the benefit of our staff and the public who are interested in a faithful and unbiassed record of everything relating to the progress of telegraphy and electricity. It is not carried on for the purpose of putting money into our pockets. (Cheers.)

Captain GOODSALL rose again to address the meeting, but

The CHAIRMAN said: You have spoken, and I will not answer you further.

Digitized by Google

Captain GOODSALL: You said you would answer all my questions. I asked how many months this £1,500 represented for the "Chiltern" in dock in London.

The CHAIRMAN: I think I must now make a statement again. I thought the gentleman who has just been addressing you had more taste and more respect for himself than to force me to make this statement. He has come forward to-day with very frivolous questions—so frivolous that I am exceedingly sorry that he should ever have been an employé of this Company. He is not so now. As I said at the last meeting, and as I say now, he left the Company for the Company's good. I am sure the shareholders will not listen to a man who comes here to put questions as to which there is no point or purpose, but simply, as he supposes, to give us annoyance.

Captain GOODSALL: I have asked a simple question—why do you not answer it?

The CHAIRMAN: I think I have replied to the gentleman who spoke about the reduction of the rates. We have had no recovery at all for the reduction we made in the Indian rates some time ago; in fact, the reduction in those rates has caused the traffic, instead of growing, rather to fall off—not that the trade has gone down, but that the cleverness of the merchants enabled them to conduct their business with fewer words than before. I have had a great deal of experience in mercantile life, and if you were to ask some of the merchants you would be astonished at the enormous amount of matter which they put into two or three words, and after all these two or three words amount to a comparatively small sum. If we were earning now what we believed we should earn when we put out our first prospectus, we should be earning over cent. per cent. The merchants have been so keen that I do not see where we can reduce our charges. At the same time, if we can see that we can do so, we shall be only too glad to reduce the tariff. So far, however, the reduction of the tariffs has not increased our earnings, but rather the reverse.

Mr. MILLIGAN: I will convey your remarks to my friends.

The CHAIRMAN: As to the question of the proxies, we have 7,000 shareholders—the Secretary tells me that we have 10,000, which shows how popular our Company is. Now there are here to-day probably 100 persons. Many of the shareholders cannot come here; they are scattered all over the kingdom. Would it be just to them to be unrepresented at these meetings? We do not charge the Company with the cost of the proxies. We send them out to the shareholders who cannot attend, and only to the shareholders who hold 100 shares or more. We do not send them to small shareholders. The Board pay for the proxies themselves in order that those shareholders who are absent may be represented. I think I have replied to all the questions that have been put, and I hope in a satisfactory manner.

Captain GOODSALL: You have not answered my question.

The CHAIRMAN: Those in favour of the motion please to signify the same in the usual manner. To the contrary. The resolution is carried unanimously.

Captain GOODSALL: Why do you not answer my question?

Dr. WALLER: Placed in the disagreeable position that you are in, it is as well that I did not speak; but I had intended to speak before the resolution was passed. The observations I should have made would now perhaps be irrelevant. I will, therefore, only say that I am very glad indeed that I desired the questions which had been put should be replied to before we proceeded further. The answers have been just what I and everyone else expected. I think the shareholders will agree that this gentleman has enlivened our meeting to-day as he did on the last occasion. I had intended to make some other observations, but I will say nothing further now.

The CHAIRMAN: That is all the business of the meeting.

Dr. WALLER: There is one thing I wish to say, however it may meet the views of others. I have often been told this—"Telegraphs are very good while they last, but do you not think if one of the nations were at war with England the telegraphs would be cut?" The observation you made to-day is a great answer to that. You told us that in submarine telegraphy there is now international co-operation. From the moment that has been so no country will cut the cables because they would be cutting them against themselves. And I shall be able to make that answer to those who tell me that the cables will be worth nothing in the event of war. "Yes," I shall tell them, "they will be, because all the parties are interested in keeping the cables going."

The CHAIRMAN: The business of the meeting is at an end, gentlemen.

Mr. JOHN NEWTON: I have much pleasure in rising to move a vote of thanks to the Chairman and Directors. I do so because I have been in the past one of the most persistent critics of the Chairman. I may say a few words as to this gentleman who interrupted the meeting with entirely personal questions.

Captain GOODSALL: Not at all.

Mr. NEWTON: The questions he put did not arise out of the business of the meeting. I have interrupted the meetings of the Company in times past with personal questions, but the personal questions I have raised have always been on the immediate action of the Directors to the shareholders, and to me in this room. This is entirely an administrative question as between the directors representing us and an old official of the Company, I claim that no past official should continue to interrupt these meetings by such questions, because, bear in mind, they are not questions put in the sense of enlightenment to us, but questions put in order to make a statement of a personal grievance. We should be very delighted to hear him, perhaps, for, as one shareholder said, he has enlivened the monotony of our meetings—a monotony arising from our success. There is no doubt, however, that the success of the Company should prevent you from hearing questions of that kind. There is only one little point on which I disagree with the Directors—that is as to issuing a fresh class of stock. I have a strong opinion on that matter, and when the time arrives I shall make known my views. I rose, however, to propose a vote of thanks to you, as you are entitled to congratulation on the great success of the Company. When you can issue your shares at a premium and put out Four per Cent. Bonds at par, as you do, there is nothing to be said. I only hold one share in this Company, but I am interested in the Globe and the Eastern Extension. I beg to move a vote of thanks to the Chairman and Directors.

Dr. WALLER: I beg to second the resolution.

The SOLICITOR (Mr. Burt): Gentlemen, it has been moved and seconded, that the thanks of the meeting be given to the Chairman and Directors for their satisfactory management of the affairs of the Company during the past year, and to Sir John Pender for the satisfactory way in which he has conducted the business of the meeting to-day.

The resolution was carried.

The CHAIRMAN: I beg to thank you, gentlemen, on behalf of myself and my colleagues. We have, I am sure, tried to deserve your confidence, and I am very pleased to see to-day that we have got it.

The proceedings then terminated.

The Anglo-American Brush Electric Light Corporation (Limited).

An extraordinary general meeting of the shareholders of this Corporation was held at the Cannon-street Hotel on the 22nd inst., under the presidency of the Lord Thurlow.

The MANAGER and SECRETARY (Mr. E. Garcke) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I can only say it gives me great pleasure to come here to-day with the programme in our report to explain to you. It is a programme that has been compiled with a great deal of care and deliberation, and I am bound to say that it consults, in my opinion, your interests most closely, and I think I may say on behalf of every member of this Board that we consider that it cannot do other than very greatly advance the value of the stock you hold, and that on the other hand if you do not pass these resolutions and adopt the course we recommend we consider you will be standing entirely in your own light. The report is very exhaustive, and, I think, gives you particulars on every point, and I do not think it will be necessary to repeat what it contains. It divides itself or may be divided, roughly speaking, under five distinct points, all of them of very great importance. The first deals with the question of litigation, which I am thankful to say is happily at an end. The second point deals with the reconstruction of the Company, which it was not possible to proceed with until the important question of litigation, and especially the Edison and Swan litigation, had been satisfactorily settled. The third point is the amalgamation with the Falcon Company. The fourth point relates to the proposed amalgamation with the Australasian Company; and the fifth point which I desire to call your attention to a little later on is the prospects of the reconstructed Company, which is, after all, the absorbing matter to us. Now, first as regards litigation: that is under two heads. There is the Edison and Swan litigation, which has been a source of tremendous anxiety to us for the past two or three years, and not unnaturally so; and I believe it has been of equal anxiety to the Edison and Swan people. That has been, a matter of practically vital importance to the Corporation. Besides, we have a smaller action still pending with regard to the compound winding of dynamos. That is a matter of practically such trifling importance that I do not think it is necessary to say more than a few words with regard to it. In the case of the Edison and Swan, the settlement we have arrived at, and which could not have been arrived at without a great deal of mutual compromise, I maintain is, if not quite as favourable as any of you might yourselves dictate, practically as favourable as it was in our power to secure. We had the alternative of proceeding to the bitter end. We had the alternative of going to the House of Lords, which we had expressed our intention of doing. That, however, would have been a very serious step. I think, indeed I know, that the majority of this Board and a very large number of the shareholders were of opinion that if we had gone to the House of Lords we should have won our case. But there is always some uncertainty in legal proceedings, and there is a possibility, greater or smaller, that we might have lost the case, and had we lost it I have no hesitation in saying that the position of this Company would have been desperate. The damages would have been excessive. We should have lost, and I think justly lost, the confidence of the shareholders, which we have hitherto possessed to, I think I may say, such a great extent, and for which we are duly grateful. I have myself felt, and several of my colleagues have felt, that had we pursued that obstinate policy, and fought this matter out in the House of Lords, in the event of its going against us the doom of this Corporation would practically have been sealed. We did not feel it wise to risk that, especially when we had gentlemen representing the Edison and Swan Company—who, after all, were reasonable men—who also deprecated final resort to the ultimate Court of Appeal. The result was we agreed upon the terms you are aware of, and under these terms honour is saved on both sides. The valuable patents of Mr. Lane-Fox are not only maintained, but the Edison and Swan Company take a license under them, and recognise their validity. On our part we give up manufacturing the lamps, which, up to this time, whatever it may be in the future, has not been a source of very large profit. We are to get lamps from the Edison and Swan Company on the most favoured terms, and they are to pay us a royalty. I hope that, having regard to the whole circumstances of the case, and to the very large issues involved, you will agree with me that we have acted wisely on this occasion in preferring half a loaf to the chance of no bread at all, and in making the terms in respect to both parties which we have made with the Edison and Swan Company. One word about the other litigation—the compound-winding litigation, which I said just now was a comparatively trifling action; and so it is when I point out to you that it stands to us in a very different position from that in connection

Digitized by Google

with the Edison and Swan Company. In the Edison and Swan action they came to us for damages for, as they contended, infringing their patents. We had a counter action, but that does not matter. They came to us for damages, and if we had lost that action we should have had to pay most exemplary damages. In the compound-winding case it is the other way. We hold that they have infringed our patents, and if we win we shall get exemplary damages from them. Then the costs of conducting this action—the compound-wound action—are trifling compared with the gigantic expenses of the Edison and Swan case. For that reason, and because we are advised we are in the right, we have given notice of appeal against the decision of the Scotch Court. You are aware that the decision in the English Court was in our favour. In the Scotch Court it is adverse, and we have now the Court of Appeal. The position of the Patent Law with respect to England and Scotland is one that is recognised as anomalous, and I think I am not far wrong in saying that some remedy for the existing state of things in this matter will not be long delayed, and when Scotch and English Patent Law will be put on a satisfactory footing. The loss of our case which we have sustained in the Scotch Court is due, I think, to the anomalous position of the law at present. That is all I have to say on the subject of litigation. I now come to the perhaps more interesting subject of the reconstruction of the Company. One or two shareholders have asked if it was necessary to reconstruct the Company. I can answer that question very simply. Every company has, as you know, Articles of Association, and what is more a Memorandum. You can alter your Articles of Association, but not your Memorandum, and our Memorandum is not wide enough to enable us with perfect legality, according to our careful lawyer's opinion, to embark in engineering business. You also know that engineering business occupies now almost the lion's share of electrical work, and to separate the two things is commercially impossible. When this Memorandum was drawn up that was not foreseen, not fully realised, and that being so it was necessary for us, to enable us to compete with them upon equal terms—it was necessary for us to have an absolute legal basis to work this extended business upon. At present the frames, the heavy casting of our dynamos, we have obtained from various founders; the engines also we have had made outside. With these works we propose to acquire we shall do away with the middlemen and get the profits by so doing. I say again, if we did not do so we could not compete on equal terms with the firms which are about to do this business. I think that will be a satisfactory reason, at least it is a compulsory one, for winding up the Company and forming a new one. There are other reasons behind, and advantages which we can gain, by winding up this Company and forming a new one. We can, for one thing, divide our capital in a more satisfactory form. We can have Preference Shares and Ordinary Shares, and it is proposed to give for each share held by you up to the present moment one Preference and one Ordinary Share. That will enable us in bad times almost to secure, I think, to you the certainty of a good dividend on your Preference Shares, and I also hope—and I hope not without a considerable amount of reason—that you will have a handsome dividend on your Ordinary Shares, perhaps after the first six months' working. Everything is in our favour in the formation of a new company. We shall have all the experience of the past. We have our old well-trained staff, whose names have become household words, I venture to say, in the electrical world, and at the same time we shall have all the energy and "go" of a new concern. There are other minor points which render it desirable in amalgamating, for instance, with the Falcon and Australasian Companies. It is easier to effect terms, and more favourable terms, starting afresh and with a new company than if we were grafted on the old company. Everything therefore, in my opinion, combines in our favour. Several letters I have received from the shareholders have approved one proposal that we have made, and that is calling up the £1 which is not paid on some of our shares. I think they are very wise in approving that course. I hold some of these shares myself, and I agree that it is wise to call up that £1 upon the shares which will then become equally saleable in the inevitable "boom" that is going to take place in electrical shares. That is, perhaps, sufficient to say at the present moment about amalgamation, though, as I said at the outset, I shall be happy to answer as fully as I can any question that may be asked of me. With regard to the Falcon Works at Loughborough, they have been visited by several of the Directors. We have taken experts to them, and it is a dividend-paying concern. So far as we know, everything is in its favour. It has the reputation of having turned out good engines, and its machinery is all erected on approved principles. It contains a certain number of acres of freehold land remarkably well situated with respect to railways and canals, and it will enable our works practically to permit of indefinite extension. It is proposed as a matter of fact to enlarge the works almost immediately, and plans are being prepared for so doing. The enlargement will not be very expensive. The acquisition of the Falcon Works, too, solves a question which has been occupying us for the last two years—the question I have spoken of more than once—of whether we should leave London and go into the country, or whether we should increase our works in London. It has solved that question by dividing our work into heavy and light, and perhaps the greater part of our light work will continue to be done at Belvedere-road, where the works are eminently suitable for our requirements. We could not leave these works without entailing on us very heavy expenses, and these works are very valuable to us as a place to show to gentlemen from the Colonies and abroad who come here with large orders to place. For that reason we retain the Belvedere Works, and a more beautiful set of works and more beautiful machinery than they now contain it would be difficult to find. The Falcon Works at Loughborough will be our mainstay for heavy work and the manufacture of the motors and other things. That being so, I will ask you to-day, if you approve generally of the programme we lay before you, to consider the purchase of these works on the terms indicated as sanctioned. It will not be in our power to ask you to pass special formal resolutions on account of the omission as to engine business in our memorandum. For that reason it is not possible as a technical point for this Company to acquire the Falcon Works, but I ask you to sanction this in a formal manner so as to enable the new Company to acquire them. As to the proposed amalgamation with the Australasian Company, the acquisition of the assets and business of our sub-companies has been in our minds for years. It so happens that Australasia is making very rapid progress in electrical science; indeed, it is certainly in advance of England and of several Continental countries. The Australasian electrical business for the next few years promises to be exceedingly large, and I have no hesitation in saying that the Australasian Company is not in a position at the present moment to reap the utmost advantage from the anticipated increase of business. Perhaps one of the reasons they came to us and that enabled negotiations to be satisfactorily carried on was owing to the circumstance that a large number of the shareholders in the one company held shares in the other, and it is their mutual interest to see the two companies working together. Without that circumstance I feel sure we should not be able to arrange satisfactory terms, and I hope there will be no hesitation on your part, or on the part of any of you, to sanction the contemplated agreement with the Australasian Company I shall have to put before you to-day—hardly in final shape, for this, that there are one or two questions not yet settled. I shall therefore ask you to accept the agreement with or without modification, it being understood that there will be some modifications. That I think is all I need say about the Australasian Company. As regards the prospects of this Company, I think if you pass these resolutions our future is practically assured. Electric lighting and electric work generally are in a very different position from what they were two or three years ago. The best proof of that is the readiness with which capital is subscribed in England for these large undertakings, and it is only by bringing a large company into existence, as this will be, that we can hold our own in the electrical world. This is a way of doing that in a manner that should be satisfactory to all concerned, and there is no "watering" of your capital. Electrical companies have grown wiser by experience. You no longer see enormous sums of money given for patents, and there is no fear now of any capital you subscribe being absorbed in that direction. You may say that electrical companies now have sown their wild oats and addressed themselves to paying business, which is to become a recognised business like any other in the City of London, and I know of no reason why it should not be equally remunerative. If the new Company does not pay a dividend in the first six months I shall not venture to come before you. I pledge myself, in fact, that it will pay a dividend, and if it does not I shall disappear, because I shall consider that I have led you astray. I am very grateful to you for the confidence you have placed in me as chairman during the last few years. Without it we could not have surmounted the difficulties and anxieties in which we have been placed. As regards the Board, it is not proposed to largely increase their number. The Board at the present moment is not a large one. It was larger formerly. The vacancies have not been filled as they have occurred. The Board now is a small one, and not too large for its present requirements. It will be desirable to increase it by two members—one representing the Falcon Works (that is agreed on) and one representing the Australasian business. Beyond that I think there will be no intention to increase the Board. I do not propose at the present time that the Board should be increased—I venture to say that because I have received two or three letters from shareholders who expressed a hope that the Board will be kept within moderate limits. Before I put these resolutions I will now ask you to state frankly any objection that you may have to the course we propose.

Mr. MARKS desired the Chairman to give an undertaking on the part of the Directors that the unallotted part of the capital would not be sold under par.

The CHAIRMAN: It is illegal to do so.

Mr. MARKS: But by paying a larger amount of commission you might do so.

The SOLICITOR (Mr. Renshaw): You cannot issue shares at a discount now.

Mr. MARKS (continuing) asked if any debts of the Australasian Company had to be taken over. He also inquired the total law expenses, and whether there was almost a certainty now that the expenditure would cease.

Mr. LANE-FOX said he wished to take that opportunity of repudiating the idea that the Edison and Swan Company were entitled to the sole right to manufacture incandescent lamps. He wished to let it be clearly understood that he did not consider himself bound by the agreement or compromise which the Brush Corporation had entered into. He considered the incandescent lamp a matter of vital importance to the progress and welfare of electrical industry, and that it would be a very serious disadvantage to the prospects of the industry if the manufacture of the lamp were to be in the hands of any one company. After the important judgment of Mr. Justice Kay, he did not consider himself bound to leave the manufacture of the lamp solely in the hands of the Edison and Swan Company. He intended, as soon as he could get an opportunity, to himself start manufacturing, and he thought it important that he should make that announcement. With respect to the merits of the compromise, the Chairman had stated that it was the best possible arrangement that could be made under the circumstances; but the circumstances were very peculiar owing to this, that the Directors of the Brush Company had been under two fires as it were. They had been in antagonism with himself, while at the same time they had been opposed to the Edison and Swan Company. To one party they had said that his (the speaker's) inventions were of the utmost importance, and that they were anterior to anything that the Edison and Swan Company did, while to himself they had said that his inventions were of no importance at all and

Digitized by Google

that they had lost money by them. He might say as to the Falcon Company that it seemed rather strange to him that a company that was going down hill, paying less and less, should be bought up at par, and he did not know why locomotive-building works should be specially adopted for electric lighting works.

A SHAREHOLDER inquired what was to be done with the balance that would be unissued of the capital of the re-constructed company of £387,000.

Another SHAREHOLDER asked a question with reference to the responsibilities that were taken over with the Falcon and Australasian Companies.

The CHAIRMAN: In reply to Mr. Marks, I can set his mind at ease entirely with respect to any fear he may have about our issuing shares below par—at a discount. Mr. Marks may feel perfectly sure that no board of directors—certainly not this Board—would undertake such a great personal liability in these days. There have been very important decisions, rendering it illegal to issue shares at a discount.

Mr. MARKS observed that his question applied not to the present Board, in whom he had perfect confidence, but to what might happen at a future period.

The CHAIRMAN: We will consider the point very carefully, and if our legal adviser says it is advisable that we should insert such a restriction in our Articles of Association we shall do so. As regards the Australasian Company, it would be taken over with a sworn statement of its liabilities and assets. Its assets exceed its liabilities. We shall only be liable for those reported to us and sworn to before we take over the Company. From that point of view there is no cause for anxiety. With reference to the total expenses of the litigation, I am not able to state the amount they will come to at present. It takes some time to tax these legal expenses very often, and for even legal gentlemen to send in their little accounts. As a matter of fact the total is not yet ascertained, but it will not be in excess of the provision made for it in our last balance-sheet. Mr. Marks also asked me to pledge my colleagues and myself not to embark in any future litigation, but that is a very difficult point to raise. People may tread on our toes. We do not mean to interfere with anybody, but if our valuable patents are infringed we must fight. There is a discretionary power we must exercise, otherwise you might proceed against us for letting our property lapse. We shall not, however, lightly enter into litigation, but we must jealously guard our property. Lawsuits, it may be remembered, vary very much. It is not every law suit that partakes of such gigantic proportions as that with the Edison and Swan Company. In reply to Mr. Lane-Fox, whom I am very glad to see here to-day, I never can be, I fear, quite in unison with him in the views he holds on these points. As to Mr. Lane-Fox establishing a lamp factory of his own, he is at perfect liberty to do that, taking his own risk. If I might venture, however, to give him a word of advice it would be to approach the Edison and Swan Company and see what could be got out of them. If he considers he has any grievance, and would lay it fairly before Mr. Forbes and Mr. Leyland, and the other gentlemen belonging to that Company, I have no hesitation in expressing my belief that they would be ready and willing to meet him in a proper and fair spirit. As regards the remark he made with reference to our purchase of the Falcon Works at a very high figure, I desire to point out that the figure is nothing like the par value at all, or nothing like the money spent on those works. As a matter of fact, those works are to be acquired at a very moderate figure indeed. To that I must add (and this is an important point) that we are paying for those works entirely in shares of this Company. That shows the amount of esteem in which our shares are held by persons outside the Company. If our shares were not considered a valuable property it is only fair to assume that the proprietors of the works would not have entered into this arrangement, but they see the advantage of it. As to the manufacture of locomotives, which they had rather carried on, that special branch will cease. We shall not manufacture locomotives unless we see our way to very remunerative contracts. What we propose to make at these works are engines of electrical machinery, for electricity cannot be generated without the engines, motors, and other things of large and heavy dimensions which we propose to make at these works. With reference to the question of unissued capital, that will remain available for issue at a future period. I hope that will be done at a premium. I only hope we may be called upon to issue that capital very shortly at a large premium. He then proposed resolutions giving the Directors power to enter into the proposed arrangement with the Australasian Company.

These were seconded and carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. NOEL, the following resolution was also carried unanimously:—

"*That it is desirable to reconstruct the Anglo-American Brush Electric Light Corporation (Limited), and that with a view thereto the Corporation be wound up voluntarily and that J. B. Braithwaite, jun., and E. Garcke, be, and they are hereby, appointed liquidators for the purposes of such winding up.*"

The CHAIRMAN next moved, and Mr. SELIGMANN seconded, the fourth resolution, as follows, which was carried unanimously:—

"*That the said liquidators be, and they are hereby, authorised to consent if required to the registration of a new company to be named 'The Brush Electrical Engineering Company (Limited),' with a Memorandum and Articles of Association which have already been prepared with the approval of the Directors of the Corporation, but which are to be subject to such alterations and modifications, if any, as may be found expedient.*"

On the motion of the CHAIRMAN, seconded by Mr. SELIGMANN, the fifth and last resolution, as follows, was put and carried unanimously:—

"*That the Draft Agreement submitted to this meeting and initialled by the Chairman for the transfer of the business and property of this Corporation to the new Company shall be, and the same is hereby, approved, and that pursuant to Section* 161 *of the Companies Act*, 1862, *the liquidators shall be, and they are hereby, authorised to enter into an agreement with such new Company (when incorporated) in the terms of the said draft and generally to carry the same into effect with such (if any) modifications as the liquidators may be expedient.*"

The CHAIRMAN: That concludes all the business of this meeting, and I can only say we will summon a further meeting to confirm these resolutions with the least possible delay.

On the motion of Mr. MARKS, seconded by Mr. SELIGMANN, a vote of thanks to the Chairman and Directors was unanimously agreed to.

The CHAIRMAN having briefly replied, the proceedings terminated.

The Australasian Electric Light, Power, and Storage Company (Limited).

An extraordinary general meeting of the shareholders of this Company was held at the offices of the Company, 39, Coleman-street, E.C., on the 23rd inst., for the purpose of considering a proposed sale of the property and assets of the Company to the Anglo-American Brush Electric Light Corporation (Limited). Mr. B. H. Van Tromp presided.

The SECRETARY (Mr. J. H. Duncan) having read the notice calling the meeting,

The CHAIRMAN, said having regard to the very full and concise statement which has been sent to you through the post by a circular issued not only by this Company but by the Brush Company, in which the scheme for the amalgamation of this Company with the Brush Company is fully set forth and explained, I do not think it will be necessary for me to enlarge on it to any extent on this occasion. I may say that for the last two or three years it has been manifest to the shareholders that what we wanted to make this Company a success, and what we required to push our patents in Australia and the other colonies, was money. We were unable to go on with the undertaking in the manner which we desired in consequence of being crippled for want of capital. At our meeting held at Winchester House in 1887 I told the shareholders what our position was, and several of the shareholders on that occasion said that they were willing, so far as they were able, to find their proportion of any new capital that might be proposed to be raised. The same question arose in 1888 when we met in this house, and it was suggested that a committee of shareholders should be appointed to confer with the Board as to a scheme by which some fresh capital might be raised, because we knew that by the acquisition of the Edison patents we had very valuable inventions which could be made into a remunerative property if we had only the means of working them. We were, therefore, anxious to put some more money into the concern by way of raising new capital in the colonies and Australia in which we had an interest amounting to one-third, and by launching out in some new undertaking in India, Africa, or New Zealand, and see whether we could not produce a dividend-paying concern for you. We considered it was necessary to do this. If you remember, in January last, in pursuance of the suggestion that we made at the previous meeting, we prepared a scheme for the reconstruction of this Company and the raising of additional capital. The nature of that scheme was circulated among the shareholders, and I am obliged to confess to you that the result was not sufficiently satisfactory to justify our carrying it out. The consequence was that in the absence of money we were obliged to look around and find a partner having capital, and having the means of raising more if it was desirable. We did so, and eventually we came into communication with the Anglo-American Brush Company, which, as you know, had their meeting yesterday, which has been fully reported in the newspapers. They have passed a resolution in which they fully approve, in substance if not in detail, of the scheme laid before you. That being so, and having regard to the position we occupy, and the difficulty we have of raising more money while our shares are at a discount, as well as to the fact that our assets are not sufficient to justify our spending money on a very bold scale, we felt that it would be better to amalgamate with a Company having a large capital, and capable of infusing new blood into our undertaking. The Anglo-American Brush Company have the power to raise capital to the extent of three-quarters of a million. They have issued between £200,000 and £300,000, and they have also debentures to the amount of £75,000. The Chairman of the Anglo-American Brush Company said yesterday that, if within the next six months he did not pay a fair, if not a handsome dividend, that he would absolutely disappear from the scene. In that Company's prosperity we shall of course participate, for we are to hold £45,000 of their stock, and we shall share equally with them their profits. If they pay 10 per cent. on the capital which was originally theirs, on that proportion of it which they have given to us we shall also get 10 per cent. We shall have all the advantage of the capital that they will bring in to carry out the operations in Australia, and to work the Edison lamp out there and in India. I need not say that this subject has engaged the attention of the Directors for months past. We have worked day by day in this as in other matters for years, and I need hardly remark that it was a matter of great disappointment to us, after labouring hard as we did, and trying to do all that we could for the Company, that we saw, in the absence of money at our back, that it was absolutely useless to try and force a large business anywhere. That being the case we considered it was best to make this arrangement, and I trust you will concur in it. With regard to the agreement certain technical difficulties have arisen, but I do not think that they are in any way insurmountable, and I would ask you to be kind enough to pass the first resolution to authorise us to carry out the agreement as prepared and agreed

Digitized by Google

to by us with such modifications as we may consider it desirable to make. I need not say that, if the modifications be of a very drastic character, that would be a matter on which it would be necessary to send out to you another circular in order to consult you. I ask you, therefore, to be kind enough to pass the resolution to-day, leaving it to the Directors to do the best they can to carry the matter through to your satisfaction. He concluded by moving the following resolution :—

"*It is hereby resolved to adopt, ratify, and confirm the agreement, dated the 12th day of July, 1889, and made between the Australasian Electric Light, Power, and Storage Company, of the one part, and the Anglo-American Brush Electric Light Corporation (Limited), of the other part; and the Directors are hereby authorised and requested to do all things that may be necessary for the purpose of giving effect to the said agreement, and carrying out the provisions thereof, either with or without modification.*"

Mr. F. ISAAC seconded the motion.

The SECRETARY, in reply to a Shareholder, said that the deferred shares were not entitled to anything under the original contract of amalgamation with the Edison Company until the other shares had reached par.

The CHAIRMAN, replying to Mr. Brown, said :—The Anglo-American Brush Company are going to reconstitute their Company and to take power to use electricity for the purposes of traction on tramways, &c., and that is why they had entered into an arrangement for the purchase of the Falcon Works, where, among other things, they are going to manufacture machinery to that end. I may say also that we are to hand over, if this arrangement is carried out, everything that we possess, not only the power patents, but all the patents that we have acquired. There are companies in England who are now making experiments with the view of using electricity for motive power on tramways. I myself, as chairman of a tramway company with a capital of £500,000, inspected a system at Canning Town, and, so far as I was able to judge, it was a perfect success, and I believe it is looked forward to with the greatest anxiety by shareholders of tramway companies. It is confidently anticipated that the shares will be at a premium. The fully-paid Anglo-American Company's £5 share is quoted at 4¼ to 4⅜. Our shares if we carry out this arrangement will rank equally with theirs.

Mr. BROWN : What is the value of your shares at the present time ?

The CHAIRMAN : The best test is what you can sell them for. Probably you will get 30s. for them if this arrangement is carried out. The Brush people talk of large dividends. They are looking forward to a much better condition of things. I need not say that the misfortune of this Company was that in the first years of our existence no less a sum than £87,000 of capital had absolutely disappeared out of £120,000, so that we were left with only about £30,000 to carry on our operations. We do not ask you to pass resolution No. 2 on the circular to-day. We think it would be an unwise thing to rush into liquidation until we are absolutely sure as to our position with regard to the other Company. We shall do nothing to materially change the condition of things without consulting you.

The resolution was then put to the meeting and unanimously adopted, and the Chairman having been thanked for presiding, the proceedings terminated.

The Falcon Engine and Car Works (Limited).

An extraordinary meeting of this Company was held at the offices, 41, Coleman-street, London, E.C., on Tuesday last. Mr. W. W. Duncan (Chairman of the Company) presided.

The CHAIRMAN, in the course of his remarks, said they had met for the purpose of getting the shareholders' consent to the sale of the Company, with all its assets and liabilities, to the Brush Electrical Engineering Company, which is a new company to be formed to embrace the Anglo-American Brush Electric Light Corporation, the Falcon Company, and the Australasian Electric Light Company. The Directors had for some considerable time been carefully and anxiously considering in what manner they could most usefully and advantageously extend the scope of the works and business of this undertaking. This policy had been dictated and, indeed, forced upon us by the fact that we found it impossible to keep our engineering department fully employed. Steam locomotives on tramways, especially in this country, have been lately to some extent in disfavour, and there has consequently been no extension of the system, and therefore an appreciably diminishing number of orders for tramway engines. Our car department has been kept fairly well in full work, but here again we have to meet with pretty severe competition, and all the large tramway companies now make their own cars. The necessity was therefore forced upon us to endeavour to embrace other work for which our factories were suitable, and we have for the last eighteen months been diligently looking into various matters and businesses that have come under our observation, with this object in view. In this manner we got into negotiation with the Brush Company, who were anxious to secure larger works, as their business was rapidly extending, and, moreover, they entertain the question of bringing the Company into prominence in connection with electrical motive-power on tramways, which there is no doubt is now imminent. The negotiations have been proceeding for some time, and have resulted in the scheme which is now before you, and which we have the greatest confidence in recommending you to adopt. In our negotiations with the Brush Company the Directors had done the best they could for the shareholders, and it was now for them to decide whether they would take it or leave it. The Brush Company has thoroughly established itself in the front rank of companies connected with electricity in all its branches, and I am firmly of opinion that those companies which have managed to live through and contend against the difficulties that have presented themselves in this enterprise are now about to reap a rich harvest. It may be argued by some of you that we are about to hand you over to a non-dividend-paying company. This is true in fact; but the only reason why the Brush Company did not pay a dividend last year was in consequence of a legal action which was hanging over it, and which has since been settled. In consequence of the absorption of the Australasian Company, it will be able to extend its business in Australia, New Zealand, South Africa and India, where there is undoubtedly a most promising and lucrative field for electrical lighting and electricity generally. He thought they would agree that the Directors, in proposing this bargain, had disregarded all thought of what were their individual interests, as of course if you adopt the scheme they lose their position as Directors without any compensation; but they desired not credit for this, as they had only done what they considered they were bound to do as the trustees for the shareholders. The whole business was to be transferred to the Brush Company, including, of course, all accrued profits of the Falcon Company, and it was not, therefore, in the power of the Directors to declare any dividend.

Mr. SUTTON expressed his disappointment that there was not to be a dividend upon the Preference Shares, and, as one of the auditors, had made it his business to call upon the secretary to ask for some explanations, as neither of these companies were paying dividends. He did not consider that the prospects of the Brush Company were very bright, but believed that electricity would come to the front, and had, indeed, always believed in it. This being so, he would not oppose the scheme, but would throw upon the Directors the responsibility of recommending the course, as he had every confidence that they would not present the scheme if they did not believe it to be in the shareholders' interest.

The Rev. W. J. STOBART stated that he was a shareholder in the Brush Company, and although he had only received one dividend from that company, he was of opinion that their business was improving from year to year. He would like to see some addition to the Board of the Brush Company, and was of opinion that it would be an advantageous thing for both companies if the amalgamation was carried through. He was also of opinion that there was an infinitely better prospect for shareholders in the future of electricity than in the future of steam locomotion or tramway extension, as people connected with tramways found that tramways in small provincial towns did not pay, while the large cities were now fully supplied. He formally proposed the resolutions.

The resolutions were seconded by Mr. SANDERSON and carried.

The CHAIRMAN remarked that it was intended to nominate Mr. Sanderson to represent the shareholders on the Board of the new Company.

Mr. SANDERSON expressed his willingness to act, and after a few further remarks as to the distribution of the new shares, the meeting closed with a vote of thanks to the Directors and officers of the Company.

Exeter Electric Light Company.

The first annual general meeting of this Company was held on Tuesday at the Athenæum, Bedford-circus, Exeter. The chair was occupied by Mr. W. H. Ellis (Chairman of Directors), and there were also present Messrs. L. J. Kennaway, H. C. Massingham (Managing Directors), C. J. D. Sanders, E. E. Braud, R. P. Bishop, J. Knill (Auditor), and H. W. Michelmore (Secretary).

The CHAIRMAN, in moving the adoption of the report, which appeared in our last issue, said they must all feel exceedingly glad after the difficulties they had gone through to find that the Company had been so well and successfully established. Their prospects were of the very best; they had already had many arc lights applied for, and at least 1,000 incandescent lamps for internal use. This, however, was nothing as compared with what they expected to get; in fact, since the report was published they had had a great number of orders for lamps besides those referred to in the report. It was only a question of capital. He believed they had got as many orders for lamps as they could execute, and it was desirable that shareholders should assist in obtaining more capital, and in inducing their friends and the public to join the Company. It was the intention of the Directors to issue a fresh circular, asking people to join, so that with more capital they might have the means of extending the supply of light. He would confidently appeal to the public to do so, even their friends in the gas company, for the latter might with advantage take shares in the Electric Light Company. He did not think for a moment that the electric light was going to injure the dividends of the gas company. He believed there was such a field for the use of gas, as well as electricity, that the more the electric light was used the more would be the demand for gas. As years went on the cry would be for "more light," and, instead of being losers, gas companies, as well as themselves, would be gainers. He trusted that the shareholders and the public would respond in such a manner as to enable the Company to supply the large field before them.

Mr. MASSINGHAM seconded. He endorsed the remarks of the Chairman on the question of the electric light in relation to health. The electric light was certainly worth considerably more than either candle, oil, or gas, and the price at which they proposed to supply it would, he thought, compare very favourably with that of other illuminants. He also agreed with the Chairman that there was plenty of room for both the electric light and gas companies, in proof of which he instanced Taunton, where the electric light was introduced four years ago, and where, instead of injuring the gas company, it had created a demand for better gas lighting, and more of it. The result was that since the introduction of the electric light the gas company had sold more gas than at any previous period during their existence, and at the present time one of the shareholders of the gas company there was a director of the electric light company. With regard to the price, with the exceptions of Taunton and Bath, the electric light would be supplied in Exeter at a lower price than in any other city in the kingdom; and, so far as his knowledge went, lower than on the Continent or America. In London the prices averaged, he believed

Digitized by Google

about 100 per cent. more than the price they (the Exeter Company) charged, whilst, taking the provinces, Eastbourne, Brighton and Hastings averaged 200 per cent. more than they were charging at Exeter. They had started in Exeter on a totally different footing to the speculative companies which had been established in some places. It was started with a comparatively small capital, which they hoped gradually to increase as the business extended. He thought they had a very bright future before them.

The report was unanimously adopted.

The SECRETARY pointed out that while the Company would prove a benefit to the city on the score of health, it would also be a financial success and pay substantial dividends.

Mr. MASSINGHAM added that in the case of the Taunton Company a share had never passed hands at less than par; and at the present time they were rapidly changing hands at 5 per cent. premium.

On the motion of Mr. KNILL, seconded by Mr. BISHOP, a vote of thanks was accorded the Chairman and Directors, and a similar compliment having been paid to Mr. Massingham and the Secretary, the meeting terminated.

Hong Kong Electric Company.

The statutory general meeting of this Company was held at the City Hall, Hong Kong, on the 25th May, the Hon. B. Layton (Chairman) in the Chair.

After the Secretary had read the notice convening the meeting,

The CHAIRMAN said: This is merely a formal meeting called in accordance with the ordinance, and there is nothing but formal business to be put through. The capital has all been subscribed and we are going on with the contracts for the machinery. The orders are all closed and we expect the machinery to be here towards the end of the year. We have to elect two auditors, and the Directors suggest that Messrs. Stewart and Coxon be elected. We have also to elect a Director, and Mr. Davies' name has been suggested.

Mr. R. K. LEIGH proposed the election of Messrs. Stewart and Coxon as auditors.

Mr. S. L. DARBY seconded, and the motion was adopted.

The CHAIRMAN proposed the election of Mr. T. E. Davies as a Director.

Mr. LEIGH seconded, and the motion was adopted.

The CHAIRMAN: That is all the business, unless any gentleman has any questions to ask.

There being no questions, the CHAIRMAN thanked those present for their attendance, and the meeting terminated.

Anglo-American Telegraph Company (Limited).

The following is the report of the Directors of this Company to be presented to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, 50, Old Broad-street, E.C., on Tuesday, the 30th inst.:—

1. The total receipts from the 1st January to 30th June, 1889, including the estimated balance of £1,325. 13s. brought forward from the last account, are estimated at £144,992. 7s. 6d. This amount, however, is subject to revision, dependent upon the result of the law suit still pending between this company and the Paris and New York Telegraph Company. The traffic receipts show an increase, as compared with the corresponding period of last year, of £68,264, consequent upon the increase of tariff from 6d. to 1s. per word, which came into force on the 1st September, 1888.

2. The total expenses of the half-year, including repair of cables, &c., as shown by the revenue account, amount to £46,277. 6s. 6d.

3. One quarterly interim dividend of 12s. 6d. per cent. on the Ordinary Stock, and of 25s. per cent. on the Preferred Stock, was paid on the 1st May, 1889, absorbing £43,750, and a second quarterly dividend of 15s. per cent. on the Ordinary Stock and £1. 10s. per cent. on the Preferred Stock, will be paid on the 1st August, 1889, absorbing £52,500, leaving a balance of £2,465. 1s. to be carried forward to the next account.

4. The Company's repairing ss. "Minia" has been engaged during the past half-year in the repair of the Tricore Cable, and the North and South Placentia Cables, between Newfoundland and Nova Scotia; she had also repaired the Salcombe-Brest Cable, on behalf of the Submarine Telegraph Company, and after undergoing certain necessary repairs in London, and taking in cable for the partial renewal and diversion of the St. Pierre-Duxbury section, completed that work on the 12th inst.

5. With the exception of the Brest-St. Pierre Cable, which was broken on the 17th inst. in deep water, the Company's cables and land lines are in good working order.

6. The Paris Conseil de Prefecture in March last heard and gave judgment upon the technical legal points referred to them by the Court of Appeal in the action brought by this Company against the Paris and New York Telegraph Company.

The decision of the Conseil is in effect that the joint-purse agreements of 1880 and 1882 were beyond the authority given to the French Company by its concession, and that the letter of the Minister of Posts and Telegraphs of 30th December, 1886, was in the nature of an official summons to that Company to break such agreements.

The Directors, after consultation with their legal advisers in Paris and London, decided to appeal to the Conseil d'Etat against this judgment, and the necessary steps are being taken for the purpose.

7. The increase of tariff from sixpence to one shilling per word, which came into operation on the 1st September last, has approximately doubled the receipts without increasing the working expenses.

This result, so far, may be considered as fairly satisfactory, and leads the Directors to hope, that with freedom from interruption to the cables and increased business, still further improvement may be reasonably anticipated.

8. The Directors regret to announce the resignation, through failing health, of their colleague, Mr. William Barber, who has for many years occupied a seat at the Board. Mr. Samuel Barber, his son, has been appointed to fill the vacancy thus occasioned, during the remainder of the term for which his father was elected.

The Globe Telegraph and Trust Company (Limited).

The following is the report of the Directors to be presented to the sixteenth ordinary general meeting to be held at Winchester House, 50, Old Broad-street, London, E.C., on Tuesday the 30th inst., at one o'clock:—

The net revenue of the Company for the year ended the 18th July, 1889, after deduction of expenses, amounts to £188,624. 1s. 2d. which, with the balance of £2,107. 1s. 3d. brought forward, make a total of £190,731. 2s. 5d. From this amount there has been distributed the sum of £126,300. 15s. 2d. in interim dividends, leaving an available balance of £64,430. 7s. 3d.

The Directors recommend the payment of a final dividend for the year of 3s. per share on the Preference Shares, and of 4s. per share on the Ordinary Shares, making, with the former distributions, a total dividend for the year of 6 per cent., less income tax, upon the Preference and 4⅝ per cent. net upon the Ordinary Shares (against 3½ per cent. for the preceding year), and carrying forward a balance of £2,053. 16s. 5d.

As indicated in the last report, the Imperial German Government have acquired the lines of the German Union Telegraph Company of Berlin, and that company and also the German Union Telegraph and Trust Company (Limited) have been liquidated. This Company has received its proportion of the return of capital. In addition 400 shares of the French Telegraph Company, Paris to New York, have been sold; and 66 shares of the German Norwegian Cable Company have been drawn for amortisation, and paid off at par, less exchange.

Digitized by Google

The following re-investments have been made, viz.:—7,444 Eastern Telegraph Company's new Shares; £62,000 Direct Spanish Telegraph Six per Cent. Debentures; 2,700 West Coast of America Telegraph Shares (fully paid); 2,750 American Telegraph Cable Company's ($100 fully paid) Shares. Five per Cent. Guarantee of the Western Union Company of New York; 3,145 West African Telegraph Company's Shares, £10 fully paid. The income from the re-investments will, it is anticipated, show an improvement on the securities paid off.

In conformity with the Articles of Association, Sir John Pender, K.C.M.G., and Sir James Anderson, two of the Directors, retire, but, being eligible, offer themselves for re election.

The auditors, Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and Mr. William Griffith, B.A., Barrister-at-Law, also retire at the meeting, and offer themselves for re-election.

The Telephone Company of Austria (Limited).

Report of the Directors to be presented at the sixth ordinary general meeting of the Company, to be held at the offices of the Company, 53, New Broad-street, on Wednesday, the 31st inst., at 3 p.m.:—

There has been expended on capital account a further sum of £8,546. 5s. 10d. The gross receipts from all sources were £13,969. 6s. 5d.; after providing for all expenses, including £3,604. 10s. 6d. for debenture interest and preference dividend, and £2,206. 0s. 10d. for royalties and taxes to the Austrian Government, there remains a net profit of £2,352. 10s. 5d., which, with the amount, £931. 14s. 1d., brought forward from last year, leaves a balance to the credit of profit and loss account for the current year of £3,284. 4s. 6d.; this amount it is proposed to carry forward.

The Directors are much pleased to again report a continued increase in the number of subscribers to the Company's Exchanges, as shown by the following table:—

	No. of Subscribers.	Inc. over previous 12 mths.	Rental.	Inc. over previous 12 mths.
			Fl.	Fl.
31st March, 1888	2,036	..... 245	161,801	 21,618
31st March, 1889	*2,299	..... 263	182,550	 20,749

*Exclusive of 142 "Extension" Telephones, which were erected during the year, giving an additional annual rental of 4,510fl.

Installations in the towns are still progressing at the usual rate, and so far as the Board can judge seem likely to continue to do so. The calls of subscribers now average over 64,000 per week, as against 60,000 last year.

The Austrian Government having decided to run a trunk line from Vienna to Prag, your Directors are now erecting, at a very heavy cost, a new and improved switchboard at their Prag Exchange, to correspond with the system in use in Vienna. This expense was undertaken in the first instance with the view of assisting the Austrian Government in their endeavour to carry out successfully their scheme of inter-urban telephony, but will also become a productive outlay as increased and improved switchboard accommodation will, in a time not far distant, become necessary, owing to the constantly-growing number of subscribers in that city.

The question of the prolongation of the Company's concessions is now under the consideration of the Government, a very carefully considered petition having been laid before the Minister of Commerce, and it is expected that the matter will be decided this autumn.

The transmission and delivery of telegrams by the Company's Exchanges has very considerably increased during the past year, the number of messages dealt with averaging 2,150 per week, and although this service has not yet proved remunerative to the Company, its advantages indirectly are very great, and sufficient to justify its continuance.

The cordial and satisfactory relations of the Imperial Royal Government Telegraph and Postal Authorities and Municipal bodies with the Company remain unaltered.

It is with regret that the Directors have to announce the retirement from the Local Board in Austria of Mr. Joseph Wessely, owing to ill health. The thanks of the shareholders are again due to him, and very specially to Dr. Eugen Weissel, for their continued services during the past year, as also to Mr. R. Howard Krause for the highly satisfactory manner in which he continues to perform his duties as general manager.

Mr. C. L. W. Fitz-Gerald retires by rotation from the Board, but being eligible, offers himself for re-election.

Your Directors, to meet the wishes of the Consolidated Telephone Construction and Maintenance Company (Limited), have invited Mr. Joseph Hicks Buckingham to a seat on the Board, and will propose his election accordingly.

The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also retire, but being eligible, offer themselves for re-election.

NEW COMPANIES REGISTERED.

WOODHOUSE AND RAWSON UNITED (LIMITED).—Registered by Johnson, Budd and Johnson, 24, Austinfriars, E.C., with a capital of £350,000 in 30,000 Preference and 40,000 Ordinary Shares of £5 each. Object—to acquire, take over and amalgamate the following businesses, and to develope the same:—(*a*) Woodhouse and Rawson (Limited), (*b*) Woodhouse and Rawson Electric Supply Company of Great Britain (Limited), (*c*) Woodhouse and Rawson Electric Manufacturing Company (Limited), (*d*) Woodhouse and Rawson Electric Contract and Maintenance Company (Limited), (*e*) C. L. Baker and Co. (Limited); any rights, trade marks, licenses, inventions, plant, stock-in-trade, and the freehold premises known as the West Kensington Hall Estate, including the factories and buildings thereon; to carry on the business of an electrical supply and manufacturing company. The first subscribers are:—Lord Aberdare, P.C., Duffryn; P. Rendson, Woodhurst, Crawley; Sir T. Farrer, Bart., Abinger, Dorking; Lieut-General Sir J. Stokes, K.C.B., Good Rest, Hayward's-heath; Sir J. Coode, K.C.M.G., 35, Norfolk-square, W.; A. J. L. Capport, K.C.I.E., 11, St. George's-terrace, S.W.; C. C. H. Vincent, C.B., 1, Grosvenor-square; F. L. Rawson, 68, Cornwall-gardens, S.W. There shall not be less than three nor more than nine directors. The first to be appointed by the subscribers to the Memorandum of Association. Qualification, 50 shares. Remuneration to be determined in general meeting.

RUSTON, PROCTOR AND CO. (LIMITED).—Registered 12th inst. by Grundy, Kershaw and Co., 19, Southampton-buildings, W.C. Capital £250,000 in £10 shares. This company is established to take over the business of engineers carried on by Joseph Ruston, at Lincoln and elsewhere, trading as Ruston, Proctor and Co. The new company takes power to construct electric, water, or gas works, to generate, store, and use electricity for any purpose, and to carry on the business of an electric lighting or storage company, or electrical engineers. Signatories (with 1 share each): Joseph Ruston, J. T. Tweed, Lincoln; G. M. Hutton, Gainsboro'; A. E. Tylor, 117, Leadenhall-street, E.C.; S. Mosley, R. F. Allured, 104, King-street, Manchester; Theodore Fry, M.P., Darlington. Messrs. Ruston, Hutton, Tylor and Fry are the first directors; qualification, £1,000 in shares or stock; the company in general meeting will determine remuneration.

CITY NOTES, &c.

BELL'S ASBESTOS COMPANY.—The directors of this company have declared an interim dividend of 12s. 6d. per share, free of income-tax, for the half-year ending June 30 last, being at the rate of 25 per cent. per annum.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended July 19, 1889, amounted to £4,167.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—At a meeting of the directors of this company, held on Wednesday, the audited accounts for the half-year to June 30 were submitted, and it was resolved, after providing for the dividend on the preference shares and placing £6,000 to the reserve fund, to recommend the payment of a dividend on the ordinary shares at the rate of 9 per cent. per annum, free of income-tax, leaving £345. 4s. 9d. to be carried forward.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 19, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,680.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

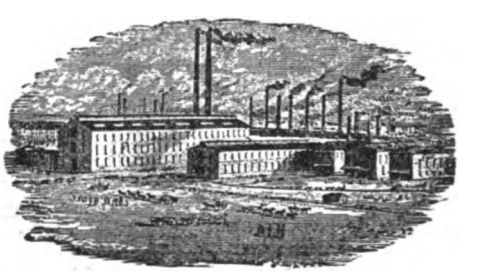
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED OURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 585.—Vol. XXIII. FRIDAY, AUGUST 2, 1889. Price Fourpence.

NOTES.

We sincerely trust that the rumours which have reached us as to the refusal of the Treasury to sanction the grant for the Standardising Laboratory are not authentic, but if what we hear be true the scheme is at present as far from realisation as ever. After the careful and explicit manner in which the necessity for the step was recently placed before Sir Michael Hicks-Beach it is not a little surprising that the purport of the scheme should continue to be so completely misunderstood. The Government seems to be labouring under the impression, first, that the scantiest accommodation and the most meagre equipment will be amply sufficient to despatch the trivial amount of business which they anticipate; and, secondly, they evidently imagine (with even greater fatuity) that the ultimate object of the movement is to gratify the tastes of a few scientific faddists akin to the species of Endowed Researchers. Nothing could possibly be further from the truth. The fact is simply that the legislation of 1882 and 1888, as well as the various Acts confirming the Provisional Orders granted by the Board of Trade, cannot possibly be carried into effect in the absence of some provision for certifying the accuracy of electrical apparatus. It is expressly stipulated in these Acts that every consumer shall be supplied with a meter, that every such meter shall be a "certified meter," and that if it is not so certified the company cannot legally recover moneys from the consumer. If the Government, therefore, declines to make adequate provision for certifiying meters, the public will soon discover that there is a serious hitch in the administration of the Electric Lighting Acts. As to what may constitute an adequate provision we shall know better at this time next year; but we have perfectly good grounds for stating our opinion that permanent arrangements for testing say 100 meters *per diem* would not long remain a superfluous provision. Finally, it should by no means be overlooked that, what with the fees to be paid for the tests, not forgetting the ammeters and voltmeters, which are almost as important as the meters themselves, the institution once set going will almost certainly become self-supporting, even if it does not speedily yield a surplus revenue.

A letter has been addressed to the Board of Trade by the London Chamber of Commerce suggesting the desirability of certain modifications in their regulations with respect to overhead wires. These regulations have received the careful attention of a Sub-Committee of the Electrical Section, and we are glad to hear that owing to the fact that the suggested alterations are few and unimportant, and are likely to be accepted by the Board of Trade, there was no necessity to trouble the President with a deputation or to call a general meeting of the Section.

We publish in another column the report of the Streets Committee of the Commissioners of Sewers on the lighting of the City. It will be seen that the Committee propose to accept the tenders of the London Electric Supply Company, the Metropolitan Electric Supply Company, and the Anglo-American Brush Corporation. The specification, which was published in our issue of February 8th, 1889, did not specify either the number or the candle-power of the lamps to be erected; but it appears from the report that 1,730 gas lamps will be displaced by 395 arcs, at a cost of £10,024 per annum, as compared with an existing expenditure of £5,530. The tender of the London Electric Supply Company amounts to £24. 3s. 10d. per arc lamp per annum (every alternate lamp being extinguished at midnight), whilst the Metropolitan and the Brush Companies each tender at the rate of £26 per lamp per annum to burn all night. It will be remembered that the concession conveys the right to supply electricity to private consumers within the same area, and that it is also provided that as soon as the profits exceed 10 per cent. upon the invested capital the surplus is to be "divided equally between the contractor and the consumer." The meeting adjourned without coming to any decision.

A seven per cent. dividend is at any time a very welcome windfall, and it is not surprising, therefore, that the meeting of the Edison-Swan Company, on Tuesday last, was of the mutually congratulatory description, especially as the dividend was accompanied by the announcement of the cessation of costly litigation and the cheering prospect of further dividends to come. The only person who is apparently left out in the cold is Mr. Edison, whose "B" shares, amounting to about one-fourth of the total capital of the company, stand in the position of Deferred shares, and are not entitled to any dividend until the "A" shares have received the full amount of seven per cent. cumulative dividend from the commencement of the company. The very modest royalty of one farthing per lamp which is to be given to the Brush Company under their Lane-Fox patents, is not likely to prove the source of a very handsome income to the recipients, unless indeed the lamp trade assumes herculean dimensions in the immediate future. This

Digitized by Google

contingency is, however, guarded against by the further stipulation that the royalties are never in any one year to exceed the sum of £375, that is to say, every lamp after the 360,000th is to be free even from the microscopic tax of the smallest coin of the realm. The cave-in of the Brush is therefore somewhat more complete than we had anticipated.

In place of the abandoned Technical Education Bill, the Government have lost no time in introducing a fresh one, which is entitled the Technical Instruction Act. The difference in title does not at first sight convey much meaning, but a glance at the new measure reveals the significance of the change; for whereas the Technical Education Bill introduced technical instruction into schools to form part of the ordinary course of education, the present Bill is designed to create technical schools where technical instruction may be had by those who care to receive it. If this Bill passes in the present Session, as we hope it may, there will not be much cause to lament the loss of the other. It is true we lose the widespread technical education which the Board Schools would have been empowered to give under the abortive Bill; but as that measure took no account of Voluntary Schools where technical education was as much needed and as loudly demanded as anywhere else, its limited application would have been used chiefly to give an unfair advantage to rate-supported schools.

As the friends of the Board Schools refused to let the Voluntary Schools have any aid out of the rates for technical educational purposes, the Government have transferred the powers to County and Borough Councils or Sanitary Boards, who may supply or aid out of the rates technical and manual instruction, but not at any elementary school to scholars receiving instruction in the obligatory or standard subjects prescribed by the Education Department. That is to say, the scholars of Board and Voluntary Schools may obtain technical instruction on neutral ground, where it may be hoped sectarian jealousies will not creep in. The rate in aid must not exceed one penny in the pound. Technical instruction is defined to mean instruction in the principles of science and art applicable to industries, or of science and art to specific industries or employments. Manual instruction is defined as meaning instruction in the use of tools, and modelling in clay, wood, or other material.

In our correspondence columns will be found an interesting letter from Mr. J. D. F. Andrews on the use of condensers in the distribution of continuous currents. Our correspondent's experiments have led to the conclusion which we expressed last week—that the method possesses little practical advantage. Mr. Andrews is, however, of opinion that in connection with alternating currents "the applications of condensers are likely to be very valuable and varied," and he instances their employment as a substitute for safety-fuses.

"Telegraphic Facts and Figures" formed the subject of a leading article in one of the Glasgow papers a few days ago. Chief among the facts on which the leader was based was the statement that 3,400 candidates had recently presented themselves for examination when there were only 15 vacancies! In reality the number of candidates who presented themselves on the occasion referred to, namely, for 16 London vacancies, was 457. On the same date 129 candidates were examined in Dublin for 6 vacancies; and in Edinburgh for 10 vacancies 122 persons were examined. Thus there were only 708 candidates for 32 vacancies instead of 3,400 for 15.

Ironmongerdom has, we believe, great hopes of partaking in the profits of the present electric lighting revival, though beyond an increase in the demand for electroliers and glass shades, we fail to see how the present "boom" will benefit the ironmonger. A clause in all the Provisional Orders now gives the supply companies power to refuse to connect unless the house-wiring has been done to their satisfaction, and the day is gone by when any bell-hanger or tinker was considered capable of properly wiring a building. We venture to think, therefore, that the "wiring" orders received by ironmongers are not likely to overwhelm them, nor do we see that the retail demand for switches and cut-outs is likely to become so extensive as to make even the most enterprising ironmongers "rich beyond the dreams of avarice."

The current issue of the *Journal* of the Institute of Electrical Engineers is one of the most interesting and valuable numbers that we have had the pleasure of receiving for a long time past. On a portion of its contents we offer some critical observations in our leading columns this week. We are sorry, however, to notice that the peculiarities of editing which have been commented upon before still continue to be as conspicuous in the *Journal* as ever. Scissors and paste are the legitimate appliances of all editors; but there is one other editorial weapon, though less talked about, equally legitimate and even more necessary to every discriminating editor, namely, the knife; and this is an instrument which appears to be wholly unknown to the Editing Committee of the Electrical Engineers' *Journal*. How, otherwise, would such irrelevant trivialities as the following be left in the reports of their learned proceedings?:—

"Mr. A.: Could you come to this corner, Mr. ———?

Prof. B.: It is difficult to do so; there is something in the way, and it is much better to be close here," &c.

The Electrical Exhibition at Bingley Hall was formally opened yesterday by Lady Randolph Churchill. A brief congratulatory speech was delivered by Lord Randolph Churchill, and Mr. Ansell, Chairman of the Executive Committee, gave a retrospect of the steps which led to the formation of the present Exhibition. The great local interest which is taken in the Exhibition was shown by the large and representative attendance at the opening ceremony.

Weybridge.—The Woking Electric Supply Company have given notice of their intention to apply for a Provisional Order for this parish.

Woking.—The Woking Electric Supply Company have given notice of their intention to apply for a Provisional Order for the parish of Woking.

Digitized by Google

Atherton.—The Lancashire and Cheshire Electricity Company have given notice to the Local Board of their intention to apply for a Provisional Order for the district.

Epping.—At the last meeting of the Epping Rural Sanitary Authority a notice was read stating that the Municipal Electric Light Company intended to apply for a Provisional Order.

Telegraphic Communication with Constantinople.—On and after the 1st of August direct telegraphic communication will be established between Vienna and Constantinople *viâ* Belgrade and Salonica.

Tchernigoff (Russia).—The Town Board of Tchernigoff has decided to adopt the electric light, and are in search of contractors for the work. Inquiries should be made of Mr. Freedman, mayor of Tchernigoff.

Bromsgrove.—The Bromsgrove Local Board has been served with notice from the Midland House-to-House Electric Lighting Company of their intention to apply for a Provisional Order to supply electricity in the district.

Postal Telegraph Promotions – Mr. Kerry, Telegraph Superintendent at Bristol, has been appointed to the Postmastership of Warrington; and Mr. West, Telegraph Superintendent at Hull, to the Postmastership of Banbury.

Bacup.—At the last meeting of the Town Council letters were read from two electric lighting companies, giving notice of intention to apply to Parliament for powers to supply electricity for lighting purposes in the borough of Bacup.

Portsmouth.—The Town Council have entered into a contract for the lighting by electricity of the esplanade from the Clarence Pier to the New Pier at East Southsea—a length of a mile and a-half on the sea front—from the 1st of August until the 8th.

Todmorden.—At the meeting of the Todmorden Local Board, on Wednesday last week, a letter was read from an electric lighting company stating that they were about to apply to the Board of Trade for electric lighting powers. The letter was referred to the Highway Committee.

Gorton.—The General Purposes Committee of the Gorton Local Board have received communications from two local electric lighting companies, giving notice of their intention to apply for a Provisional Order to supply the district with the electric light for public and private purposes.

The Electric Meter Competition.—The Committee charged with making the awards in the Electric Meter competition organised by the Municipality of Paris have commenced work, and their report may be expected within a few months' time. The only well-known competitors are Mr. Ferranti and M. Serrin.

Edison-Swan Annual Excursion.—The Edison-Swan Company's workpeople held their annual excursion on Saturday, 20th July, at Yarmouth. A very pleasant day was spent, the weather being exceptionally fine. Dinner was served to a large company in the Aquarium, after which several toasts were given and heartily drunk.

Penryn.—At the last meeting of the Town Council a letter was read from the Falmouth Gas Company stating that it was the intention of the company to make application for the necessary license to supply electricity within the area of the borough of Penryn, and asking the Council to give the matter their favourable consideration.

Electric Lighting Tenders.—The Municipality of Port Louis (Mauritius) invite tenders for lighting that town by gas or electricity. The Vestry of St. Mary Abbott's, Kensington, are also advertising for tenders for the electric lighting of a portion of the Kensington Town Hall. Further details will be found in our advertisement columns.

Penzance.—At the last meeting of the Town Council the Lighting Committee reported that a notice had been received from the Devon and Cornwall Electric Light Supply Company of their intention to apply for a Provisional Order. A similar notice had also been received from the Electric Construction and Maintenance Company.

The Edinburgh Exhibition.—On behalf of the Executive Committee formal application has been made to the Edinburgh Merchant Company for the use of ground belonging to them at Meggatland as the site of the forthcoming Electrical Exhibition. The Master has called a special meeting of the Governors to dispose of the matter.

Cowpen.—On Saturday night last Messrs. Nicholson and Jennings made a public experiment with five lights at Waterloo and Cowpen Quay, and the test proved exceptionally satisfactory. Messrs. Nicholson and Jennings commence their agreement on the 15th of August to light the township of Cowpen with 18 lamps for a term of five years at £525 per annum.

Exeter.—The Exeter Electric Lighting Company has commenced the erection of supports to carry the wires through the streets. At a recent meeting of the Town Council it was resolved that the company should be informed that the permission to erect posts in the public streets was subject to the right of the Council to withdraw it, and to require the removal of the posts at any time, on twelve months' previous notice being given, irrespective of any question other than the will of the Council.

Fairbairn's Sight-Feed Lubricator.—Woodhouse and Rawson United are now manufacturing a new form of lubricator (Fairbairn's Patent), which possesses the great advantage of being perfectly independent and applicable to any bearing. The amount of oil in the lubricator can be seen at a glance by the position of the piston-rod above the cup. The same firm have also brought out an oil filter, called the "Diamond," which should effect a considerable economy in the oil bill, and the first cost of which is very moderate.

Electrical Distribution.—The United Electrical Engineering Company have just issued a popularly written well-illustrated pamphlet, entitled "Electrical Distribution." The manifold advantages of electricity for light and power purposes are clearly and concisely set forth, and figures are given to correct erroneous impressions as to the clearness of the electric light and the unremunerative character of central station enterprise. The pamphlet forms an eminently readable and instructive little publication.

Society of Engineers.—On Tuesday last the Society of Engineers visited the Outfall Sewage Precipitation Works, now in progress at Crossness. The party proceeded from Westminster by a special steamboat, and were entertained at luncheon by the contractor, Mr. Wm. Webster. After luncheon the party were conducted over the works by Mr. F. E. Houghton (resident engineer) and Mr. Webster. The visitors were also shown Mr. Webster's electrical method of purifying sewage (see *The Electrician*, March 29, 1889, p. 588), which has now been in operation for over 12 months.

Clerkenwell Vestry.—The Vestry Clerk of St. Martin's-in-the-Fields has written asking Clerkenwell to endorse the following resolution passed by them: "Resolved, that the Vestry are of opinion the County Council have exceeded their functions in agreeing to proposals for over-riding the powers of the local authorities without affording them opportunities for considering such proposals, and that the Board of Trade, the County Council, the local authorities of the metropolis, and the members of the County Council for the Strand, be informed this Vestry approve of the objections urged by the Paddington and Chelsea Vestries against such transfer being made."

Liverpool Docks (Electric) Railway.—The contract for the Liverpool Overhead Railway Company has been let to Mr. J. W. Willans, of London, Liverpool and Manchester. This important undertaking is the first of the kind in England, though the type of railway is well known to our cousins in the New World. The total length of the railway is about six miles, and it runs parallel with the docks all the way. The structure is composed of iron girders, having a water-tight flooring for the whole length, and is carried on strong wrought-iron pillars. It is intended that the trains shall be worked electrically. The engineers are Sir Douglas Fox and Mr. J. H. Greathead.

Digitized by Google

The Regeneration of Photographic Plates.—A curious phenomenon has been observed by Mr. J. Green, and was recently described by him before the London Photographic Society. Mr. Green believes that electricity is capable of restoring an exposed plate to its primitive condition; in other words, of making an old plate as good as new. If a plate which has been exposed is placed in a slightly acid bath, and if a current is then passed through the bath for a short time, the latent image is obliterated. The reason of this is not quite clear, although the result may perhaps be attributed to the formation of peroxide of hydrogen, which causes the obliterating effect.

The Provisional Orders in the House of Lords.—The Bills confirming the Provisional Orders granted by the Board of Trade for the electric lighting of London will, it is expected, meet with a somewhat strong opposition in the House of Lords. In the case of the Westminster and West-end Orders, a serious attempt will be made to throw out the Bills in Committee, on the ground that the consent of the local authorities has not been given to these Orders. With this object in view several petitions have been lodged in the Private Bill Office of the House of Lords praying to be heard against the Bills. The London County Council will also oppose these Bills, but their opposition is directed more to the clauses than the preambles.

Maidstone.—Mr. Wm. Webster has been in negotiation with the Maidstone authorities with a view to carrying out some extensive experiments with his electrical process for the treatment of the sewage. He proposes to carry out the experiments at a cost of £200, such sum to be paid by the town if the experiments are successful, but if not successful he will bear the cost himself. If Mr. Webster's process proves satisfactory he will then undertake to purify the sewage on an agreed sum per annum. The Local Board have agreed to fall in with Mr. Webster's proposals, and as the Local Government Board are applying pressure for some steps to be taken to prevent the River Medway from being polluted by the discharge from the town sewer, the work will be commenced without delay.

Atmospheric Electricity.—With a view of investigating more thoroughly the part played by atmospheric electricity in the formation of the nitrate compounds which exist in the air. M.M. A. Muntz and Marcano have for the last two years made, careful observations on this point at Caracas (Venezuela), where storms and electric disturbances are of great frequency and intensity. The conclusion arrived at by MM. Muntz and Marcano is that the extraordinary richness in nitrates which characterises the atmosphere in these regions can only be attributed to the very high electrical potentials usually prevalent and the frequent electrical discharges. Taking the annual rainfall of Venezuela at about one metre, the rain deposits something like 6·93 kilogrammes of nitrate per hectare (7lb. per acre), and is therefore a most valuable fertiliser.

The Pieper Semi-Incandscent Lamp.—M. Henri Pieper, jun., of Liège, has brought out a new type of semi-incandescent lamp. The lamp consists of two horizontal rods of copper, set in line with each other, but separated by a space of about $\frac{3}{10}$ths of an inch. A thin fluted carbon rod is set vertically, and rests upon the ends of the copper rod, forming a bridge across. The current passes through the copper rod and through the point of the carbon rod, which is thereby rendered brilliantly incandescent. The copper rods are supported on spring hinges, and if the carbon should break, they will rise slightly until two contacts at their outer ends come into action, thus automatically short circuiting the lamp. The wear of the copper rods is exceedingly slight, the carbon only being consumed. Some lamps of this type have been sent to the Paris Exhibition.

St. Margaret's and St. John's (Westminster) Vestry.—At a meeting of this Vestry, on Wednesday last week, Mr. Bowman Spink introduced a deputation from the City of Westminster Electrical Syndicate. The Clerk also read a letter notifying the intention of the company to apply for a license to supply electricity in the parish. They stated their willingness to light the streets at a price not exceeding the present cost of gas, to erect and maintain free of charge for twelve months lights at three important points in Victoria-street, to enable the Vestry to judge of the effect; and, should the Vestry so desire, to act as their Undertakers in respect of public lighting generally. The full capital of the syndicate was £20,000, and they had raised half that sum up to the present time. The consideration of the question was referred to the Parliamentary Committee for report.

Brighton.—At the last meeting of the Brighton Town Council it was resolved that the Town Clerk should request Mr. Shoolbred to meet the Gas Committee on an early day, with a view to his advising the Corporation as to the best course to pursue in order to provide a supply of electricity in the borough, whilst retaining for the Corporation complete control over the laying of mains and all work which would be executed in the public streets. It will be remembered that early in the year a Board of Trade inquiry was held, with the result that as Brighton had decided to supervise the electric lighting of the town, the Board of Trade did not see how they could dispense with the consent of the town in granting a Provisional Order for the Brighton Electric Light Company. The Council now find themselves compelled to undertake the business within two years, either by themselves or by letting it to others.

Electric Lighting Provisional Orders.—In the House of Commons on Friday last, in answer to Sir G. Campbell, Sir M. Hicks-Beach said that the formal consent of the Birmingham Corporation had been given to the Provisional Order for that town. The President of the Board of Trade further remarked that he would endeavour to arrange that in future either the formal consent of the local authority should be obtained, or that a special report should be made before the second reading of the confirming Bill. In the consideration of any future proposals which might come before him, he said that he would certainly take care that local authorities were not unduly harassed or hurried. It was with the very object of avoiding any such hurry that Parliament had enacted that notices should be given to local authorities on or before July 1 of all Provisional Orders applied for in respect of the ensuing Session of Parliament.

Lambeth Vestry.—At the last meeting of this Vestry the Clerk read letters from the Metropolitan Electric Supply Company, the London Electric Supply Corporation, the Electric Construction and Maintenance Company, and the House-to-House Electric Supply Company, giving notice of their intention to apply for Provisional Orders to supply electricity within the parish. He explained to the Vestry that at present two Orders had been obtained, one by the Metropolitan Company, and the other by the London Electric Supply Corporation. The former had entirely withdrawn their Order, and the streets included in the latter were only three, and the representatives of the company declined to take any further responsibility. He suggested that the matter should be referred to the Electric Lighting Committee, with power to present a petition against the London company's Order if they thought fit and proper to do so.—The suggestion was unanimously agreed to.

The Reported Atlantic Cable Combination.—"We (*Pall Mall Gazette*) are informed that there is no truth in the report that the Mackay-Bennet and the French Atlantic Cable Companies have entered into an amalgamation. As the latter company cannot even enter into a pool with the cable companies, it is obvious that it would be impossible for it to amalgamate. The visit of Mr. Ward, the New York manager of the Commercial Company, to Nova Scotia, had nothing to do with the question of amalgamation. The French company has landed its cable near Canso for the purpose of connecting with the Canadian Pacific Railway, which is now building lines in Nova Scotia. This gives the French Company a second route to the United States. As to the scheme of a new Anglo-Canadian cable with a guarantee from the Dominion, little heed is paid to it, as it is not taken seriously." For further information with regard to the last of these rumours we may refer our readers to the speech of Lord Tweeddale at the Anglo-American Telegraph Company's meeting, which we report this week.

The Preparation of Cellulose by Electrolysis.—When wood or any other similar substance is attacked by an acid, the mineral constituents of the fibre are dissolved, and the cellulose

Digitized by Google

is precipitated; the latter is, however, mixed with complex organic compounds called "selmics," and in order to obtain pure white cellulose bleaching is necessary. It seems, however, that electrolysis affords a means of securing pure cellulose by one operation. Two vessels communicating with one another, and containing a 5 per cent. aqueous solution of chloride of sodium are filled with small pieces of wood. One vessel contains the anode and the other the cathode, the whole being kept at a temperature of 120°C. Under the action of the current the chloride of sodium is split up into chlorine, which goes to the cathode, and sodium, which goes to the anode. The nascent chlorine gives rise to hydrochloric acid and hypochlorous acid. The hydrochloric acid dissolves the mineral constituents and precipitates the impure cellulose. The hypochlorous acid takes away the colouring substances by oxidising the "ulmic" constituents, and is then transformed into hydrochloric acid, which saturating the free sodium, regenerates the chloride of sodium. As it is advantageous to submit the cellulose thus formed to the action of an alkali the current is reversed. The cellulose is then washed in acidulated water and the preparation is complete, the material being white and silky.

The British Association.—The British Association meeting will open on Wednesday, September 11th, at Newcastle, and the following is the programme at present agreed upon :—

Wednesday, Sept. 11.—Horticultural show. The President, Prof. Flower's, address, 8 p.m.

Thursday, Sept. 12.—Reading of Papers in the various sections, 11 a.m. Soirée, given by the Mayor and Corporation of Newcastle, 8:30 p.m.

Friday, Sept. 13.—Reading of Papers, 11 a.m. Lecture on the "Hardening and Tempering of Steel," by Prof. Roberts-Austen, F.R.S., F.C.S., 8 p.m.

Saturday, Sept. 14.—Reading of Papers, 11 a.m. Half-day excursions. Conferring of degrees at Durham University, 2 p.m.; and invitation luncheon to 200 members of the British Association, 3 p.m. Service in Cathedral, 4 p.m. Lecture to the working classes on the "Forth Bridge," by Benjamin Baker, Esq., C.E., 8 p.m.

The lectures delivered on Saturday evenings during the week of the meeting are intended solely for the working classes; they are not included in the proceedings of the Association, and members other than officials are not eligible for admission.

Sunday, Sept. 15.—Special services at the various churches in the City.

Monday, Sept. 16.—Reading of Papers, 11 a.m. Lecture on "How Plants Maintain Themselves in the Struggle for Existence," by Walter Gardiner, Esq., M.A., F.L.S., 8 p.m.

Tuesday, Sept. 17.—Reading of Papers, 11 a.m. Soirée, given by the Local Executive Committee, 8:30 p.m.

Wednesday, Sept. 18.—Concluding general meeting, 2:30 p.m.

Thursday, Sept. 19.—Whole day excursions.

No special invitation will be required to either of the soirées, but members will be admitted on presentation of their tickets.

The Recent Thunderstorms.—The storms of last week seem by all accounts to have been of a very destructive character. The storm of the 21st ult. was chiefly confined to the Eastern counties, although Oldham and the vicinity was visited on the same date by a very heavy thunderstorm, during which numerous houses were struck and greatly damaged, amongst the number being a house in Penn-street, on the Coppice. The lightning first of all struck the roof, knocking off the chimney pots and tearing up lead around the base of the chimney stack. It then went down the chimney and burst through the wall into the front bed-room. The bed room furniture was broken up and the pictures were shattered with such force that pieces of the frames were driven into the plaster of the opposite wall. The lightning then darted through the wall into the back bed-room, making a large opening in the wall, and descended by way of the back bed-room fireplace into the kitchen. At North Walsham 20 lambs were killed by lightning. At Lincoln a house in Saul-street was struck, and a fireplace was displaced and forced out half a foot into the room. On Tuesday last week Scotland and the Midlands were visited by a severe storm, accompanied in several instances by heavy snowfalls. At Auchterless a man was killed and several persons were badly injured. At Chellaston, on the same date, a row of five houses and a house adjoining were struck by lightning, which first descended on a stack of chimneys on a cottage at the opposite end of the row to the house. It dislodged the upper part of the chimney and a portion of the gable; the lightning then passed down the roof, knocking off the tiles in its path. On reaching the spouting, which it twisted out of shape, it continued its course for about 80ft. without damage until it reached an angle of the spouting, which was torn away. It then followed the spout for about 100ft. more without doing much damage except bursting two short water conductors and making a large crack in Mr. Domleo's house. The current then passed on still further, by a slaughter-house, to a covered roadway, seriously deranging one of the walls which support the roof, and descended by the water conductor to the earth, partly destroying the conductor in its passage. From the point at which the houses were first struck to where the lightning entered the earth was about 180ft. At Buckhurst Hill last week, during a storm, a carriage was struck in the Epping New-road, and the driver was killed. Storms of exceptional severity are also reported from other parts of the provinces.

The Electricity Supply Companies Registered during the Six Months ended June 30th, 1889.—The following is, to the best of our belief, a complete list of the public companies which have been registered at Somerset House during the period from January 1st to June 30th, 1889, and whose object is wholly, or in part, the public supply of electricity. We have divided the list into "General" and "Local" Companies, but it will be seen that the former includes several whose operations are apparently confined to a limited area. The total registered capital of the General companies amounts to £2,322,105, and of the Local to £1,059,000, amounting in all to £3,381,105 :—

GENERAL.

	Registered Capital.
Electric Construction Corporation	500,000
*Galloways	250,000
*Elmore's Patent Copper Depositing Company	200,000
*Priestman Brothers	150,000
*Mudge-Marchant Engine Company	131,105
Electricity Supply Corporation	100,000
Irish House-to-House Electricity Company	100,000
Lancashire and Cheshire House-to-House Electricity Company	100,000
Midland House-to-House Electricity Company	100,000
Northern House-to-House Electricity Company	100,000
Scottish House-to-House Electricity Company	100,000
South of England House-to-House Electricity Company	100,000
Western House-to-House Electricity Company	100,000
Yorkshire House-to-House Electricity Company	100,000
Electric Trust	60,000
Laing, Wharton and Down Construction Syndicate	40,000
*Northern Press and Engineering Company	30,000
Municipal Electric Light and Power Corporation	25,000
Planet Electrical Engineering Company	20,000
*Great Marlow Water Company	16,000

LOCAL SUPPLY COMPANIES.

Birmingham House-to-House Electricity Company	£100,000
Devon and Cornwall Electricity Supply Company	100,000
Liverpool House-to-House Electricity Company	100,000
Manchester House-to-House Electricity Company	100,000
Nottingham Electric Light and Power Company	100,000
South-Western District and Thames Valley Electricity Supply Company	100,000
Sunderland and District Electricity Supply Company	100,000
Cambridge University and Town Electric Lighting Co.	50,000
Newcastle-upon-Tyne Electric Supply Company	50,000
Newcastle and District Electric Lighting Company	50,000
Portsmouth and South Hants Electricity Supply Company	50,000
Wolverhampton Electric Light and Power Company	50,000
Bath Electric Light Company	25,000
Halifax Mutual Electric Light and Power Company	20,000
Northampton Electric Light and Power Company	20,000
Woking Electric Supply Company	20,000
Pontypridd Electric Lighting Company	10,000
Croydon Electric Supply Company	5,000
Keswick Electric Light Company	5,000
Brompton Electric Fittings Company	2,000
Kingston-upon-Hull Electric Lighting and Supply Co.	1,000
Leicester Electric Light and Power Company	1,000

* These companies have taken powers to supply electricity, though the fact is not indicated in the title.

ON THE DISTRIBUTION OF ENERGY BY MEANS OF ALTERNATING CURRENTS.*

BY M. LEBLANC.

We will consider first the most obvious solution of the problem, which consists in the utilisation of the fact of the reversibility of ordinary alternate-current dynamos. We may suppose that the field magnets of the machine used as a motor are separately excited, or consist of permanent magnets; the self-induction of the circuit traversed by the alternating currents will then be very small, provided that the armature contains no iron, and the apparent resistance will not be much greater than its actual resistance. If we call I the intensity of the current in the armature, M the coefficient of mutual induction of the two circuits, and ω the angular distance through which the armature is displaced; then the motor couple F developed upon the axis will be given very approximately by the formula

$$F = I I^1 \frac{d M}{d \omega}.$$

In an ordinary alternator the armature consists of a number of pairs of bobbins identically situated around the circumference, and the field magnet presents an equal number of poles, alternately positive and negative, and are disposed in the same manner. Each time that the armature has turned through the angle which separates the axis of two consecutive poles, the coefficient M passes through the same series of values, but the sense in which the flux M I [the number of lines of force per pair of poles] traverses the armature has been changed. An equal variation of this flux will produce in the armature an E.M.F. equal and of contrary sign to that which was produced in the first instance. We can now write, in accordance with the first term of Fournier's series, $I \frac{d M}{d \omega} = \mu 1 \sin 2 \pi \frac{t}{T}$, where μ and I are two constants, T is the period—that is, twice the time which a coil takes in passing from one pair of poles to the next—and for $t = 0$ the axes of the coils of the armature coincide exactly with those of the poles of the field. In order that the couple F may always be of the same sign, it is evident that the variations of the current I must have the same period as that of $I \frac{d M}{d \omega}$. We can then write

$$F = \mu I A \left[\sin^2 2 \pi \frac{t}{T} \cos 2 \pi \phi - \sin 2 \pi \frac{t}{T} \cos 2 \pi \frac{t}{T} \sin 2 \pi \phi \right].$$

We see immediately that the mean value of this couple, the only one in which we are interested, will be given by

$$F = \tfrac{1}{2} \mu I A \cos 2 \pi \phi.$$

In order that a similar machine may be used as a motor, it is necessary that the variations of the coefficient of mutual induction of the field and the armature, and the current which traverses the latter, shall have the same period; that is to say, the speed of the motor must synchronise with that of the generator. And it can be shown that in order that the motor may tend to synchronise with the generator, it is necessary that the opposing couple upon its axis shall be less than $\frac{1}{2} \mu I A$.

Efficiency.—If R is the resistance of the armature and ρ that of the field-magnets, the quantity of heat disengaged per second in the system will be given by $\rho I^2 + \frac{1}{2} R A^2$. We here neglect the loss due to Foucault currents or hysteresis. Let us put $K = T \frac{d \omega}{d t}$, K being therefore a constant; the work done per second upon the axis of the machine will then be

$$\tfrac{1}{2} \frac{K}{T} \mu I A \cos 2 \pi \phi,$$

and the efficiency m is

$$m = \frac{K \mu I A \cos 2 \pi \phi}{K \mu I A \cos 2 \pi \phi + T (R A^2 + 2 \rho I^2)} \quad \ldots \quad (1).$$

In order to obtain a value for A, we have the following equation :—

$$E^2_0 = \left(R^2 + \frac{4 \pi^2}{T^2} L^2 \right) A^2 + \frac{K^2}{T^2} \mu^2 I^2 + \frac{2 K}{T} \mu I (R A \cos 2 \pi \phi + \frac{2 \pi}{T} L A \sin 2 \pi \phi).$$

In this expression E_0 is the maximum value of the E.M.F. Replacing the value of A from this expression in equation 1, we could get a numerical expression for the efficiency [the equation is, however, chiefly of use, in order to see in what direction the quantities vary]. We see immediately that the efficiency diminishes as the difference of phase ϕ approaches the value $\frac{1}{4}$—that is to say, as the output of the machine diminishes. As in practice we ought to prevent any sudden increase of the load, which, if it exceeds a certain limit, would arrest the motor without power to re-start, we shall be led to make the mean value of the angle ϕ tolerably large. We do not think it possible to obtain with synchronising alternators efficiencies as high as with continuous-current motors. On the other hand, unless, indeed, we employ permanent magnet machines, which are costly and cumbersome, the excitation of the field magnets presents many difficulties Lastly, there is the defect that these machines are not self-starting.

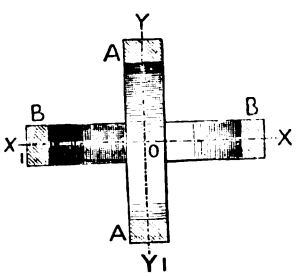

FIG. 1.

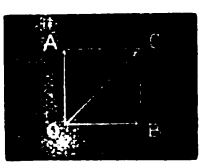

FIG. 2.

The Tesla Motor.—At nearly the same period Ferraris in Italy, Bosel in Switzerland, and Tesla in America, discovered an interesting property of magnetic fields when excited by alternating currents. Consider two concentric circular coils, A and B, making a right angle between them (Fig. 1). If we put through the coil A an alternating current, whose value is given by $I = J \sin 2 \pi \frac{t}{T}$, the magnetic force developed will be proportional to the current I_1, and will be directed along the axis O X. Now put through the coil B an alternating current having the same period T, but whose alternations differ by a certain phase ϕ. The intensity of the current can be expressed by

$$I_1 = J_1 \sin 2 \pi \left(\frac{t}{T} - \phi \right).$$

The magnetising force developed in the coil B will be proportional to I_1, and will be directed along the axis O Y, perpendicular to the axis O X. The resultant magnetic force developed at the point O will be equal at each instant to the resultant of the two forces directed along O X and O Y, and we can represent them in magnitude and direction by the right line O C (Fig. 2). If we trace the successive positions taken up by the point C during a period T, we find that the locus is an ellipse, having its centre at the point O. In the case where ϕ is $\frac{1}{4}$, the ellipse becomes a circle. The direction of the resultant magnetic force therefore rotates continuously around the point O. If we have ϕ equal to $\frac{1}{4}$, and if the magnetic permeability of the medium is the same in all azimuths, the result is the same as if we had a magnetic field of constant intensity continuously rotating around the point O. It is now easy to see that if we place a metallic disc between the coils A and B, so arranged as to be movable around an axis passing perpendicularly through O, this disc will be carried round by the rotation of the field as in the well-known experiment of Arago.

Mr. Tesla has applied this property to the construction of a motor which we represent diagrammatically in Fig. 3. A ring of iron wire divided into equal quadrants is wound with four equal coils, $a\, a_1\, b\, b_1$. The coils $a\, a_1$ are connected in the same circuit in such a manner as to develop in the ring two poles upon the line X Y. The coils $b\, b_1$ are connected in a second and

* Abstracted from *La Lumière Electrique.*

Digitized by Google

independent circuit, and produce two other poles along the line X_1 Y_1, making a right angle with the line X Y. If we send an alternating current through the coils B B_1, the magnetic field developed in the ring will be constant as regards intensity, but its direction will be turned around the point O, and will make one revolution during the current period T. Mr. Tesla places in the middle of this field a drum armature, in which each coil is independent and closes upon itself. This is a remarkable machine; it has no sliding contacts, and it may be used with currents of high tension even when it is of small dimensions. The couple increases as the quickness of rotation diminishes, and its electrical efficiency can be made as high as we wish. It presents the inconvenience of necessitating a double set of conductors in order to provide the two currents differing in phase by $\frac{1}{4}$th. The apparent coefficient of self-induction of the system

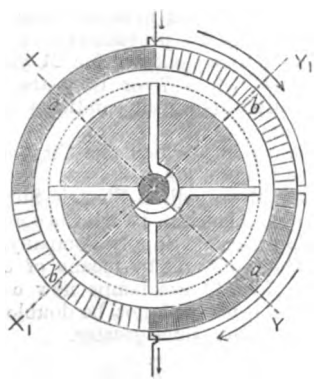

FIG. 3.

is smaller than the actual value, owing to the reaction of the armature. In order, however, that its output may be reasonably great in proportion to its size, it is necessary that the field due to the armature should be sensibly equal and of contrary sign to that of the field magnets. This condition it is impossible to realise. The actual size which a motor of this kind can attain is also limited by the effect of the enormous self-induction of the field. Finally, we do not think that the very interesting solution of Mr. Tesla will have any practical application, except, perhaps, for very small motors for domestic use.

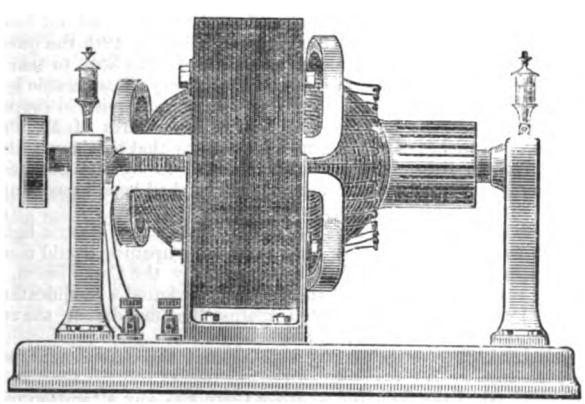

FIG. 4.

The Elihu Thomson Motor.—Prof. Elihu Thomson observed that if an electro-magnet, the coil of which was traversed by an alternating current, was placed opposite another electro-magnet, the coil of which was closed upon itself, the two mutually repelled one another. The outcome of this observation is the alternate-current motor shown in Fig. 4. In this machine, as in the Tesla motor, very high tensions can be used, since there are no sliding contacts. The apparent self-induction of the system is smaller than its actual value, owing to the reaction of the armature. Our personal experience has, however, shown us that the apparent resistance of machines of this type where supplied with currents of high frequency is far too great to allow them to be of much commercial value.

(To be continued.)

REVIEWS.

Munro and Jamieson's Pocket Book of Electrical Rules and Tables. Sixth Edition, Revised and Enlarged. (London: Charles Griffin and Co., 1889).

It is just five years since the first appearance of this invaluable publication, and since then no less than six editions have been demanded. This rapid succession of issues betokens not only the popularity and usefulness of the book, but also the determination of the authors to keep the contents as closely as possible up to date. The present edition, for instance, contains no less than 120 additional pages and 60 new figures relating for the most part to the latest developments of electrical engineering, and in particular to the applications of alternating currents. Amongst the new matter we may especially mention an excellent chapter contributed by Prof. S. P. Thompson, on the designing of dynamos, with remarks upon their installation and working, whilst Mr. Gisbert Kapp has a concise and useful Paper on transformers. Sir William Thomson's standard balances and Profs. Ayrton and Perry's sechommeter are each adequately dealt with. If any fault is to be found with this section, it is that the information is much more complete and exhaustive than would generally be looked for in a work one at least of whose *raisons d'être* is supposed to be its portability. If every subject referred to were treated upon the same liberal scale as these, the volume would speedily assume a bulkiness of aspect which would wholly belie its title. However, this is a difficulty to which probably the authors are already fully alive, and in later editions a judicious pruning will doubtless be applied in those sections wherein the losses will be felt the least. We do not mean to imply that the Sixth Edition itself is actually sinfully obese, but we do think that it approaches perilously near to that condition. The ultimate remedy will probably be a separation into two volumes, one for the Electrical Engineer and his compeers, and a second for the Telegraph Engineer, *et hoc genus omne.*

We pass on now to offer a few criticisms, more or less immaterial in character, but designed in response to the prefatorial request—a quite sincere one we are well assured—that any hints or suggestions for the improvement of the work may be unhesitatingly made known. To speak first of a minor point, we fail to appreciate the advantage of paging the new matter with the addition of an italic letter tagged on the number of the preceding page. We can only suppose that the authors wish to mislead the unwary into supposing that there are only 497 pages in the whole book, whereas the number positively exceeds 650! However, letting this pass, and coming to more important matters, we note that amidst a wide range of tables, many of which are of quite indispensable value, there are still some useful things which we seek in vain. For instance, we may reasonably ask for a table of current density per square inch, both for the Birmingham and for the standard wire gauge. Some dip and span tables for the erection of copper wire would be useful; indeed the whole section relating to overhead conductors other than iron might be considerably extended.

There is a valuable chapter by Prof. Ewing on Magnetic Measurements, containing a set of curves showing the relation between magnetising field (H) and magnetisation (I) for certain samples of iron and steel. We would suggest the desirability of supplementing this by further curves, both for wrought and cast iron, and for annealed plate and wire such as is most commonly used by the electrical engineer; and we would also add reciprocal curves showing the increase of magnetic resistance with the field intensity. The curves might perhaps be usefully supplemented with numerical tables. Some readers would no doubt like to have results in Kapp lines as well as in C.-G.-S. Such data as we here ask for would, it need hardly be said, be of immediate use in the design of dynamos, although it is perhaps true that careful men prefer to make their own preliminary tests upon the iron to be used.

Turning to another subject, we find the electric transmission of energy somewhat sparsely dealt with. There are several useful data and formulæ connected with this branch which might well find a place in these pages. The coefficients of traction which are likely to be met with in practice under given conditions should be recorded, and the simple formula for

Digitized by Google

reckoning the power required to move a given load on a given gradient at a given speed. This kind of information would be of far more use than the equations of efficiency which are only applicable to the special case where generator and motor are of the same construction.

In the next edition we shall no doubt have Sir William Thomson's Tables (or the extension by Mr. Mordey) showing the actual resistance of conductors of given area with alternating currents of given period. It is, perhaps, a little premature to call for the revision of the section dealing with lightning conductors in the present divided state of opinion upon the subject, though, according to our own view, the advice tendered would bear supplementing, and, at least, the "area of protection" superstition should disappear.

We have only one other suggestion to make at the present moment. In the index we should like to see a separate subheading "Tables," in which all the Tables would be brought together in alphabetical order, so that it could be seen at a glance what information is given in tabular form. By-the-bye, we may mention here that on page 428 will be found the British Association standard small screw gauge, the adoption of which is now under the consideration of the Electrical Trades' Section of the Chamber of Commerce.

It is quite unnecessary that we should add, in conclusion, any words of commendation in respect of the general scope and merits of the book. It is sufficient to say that it has become as indispensable to the Electrical Engineer as "Molesworth" is to the older branches of the engineering profession

THE CONTRACTS FOR THE LIGHTING OF THE CITY OF LONDON.

The following report was presented to the Commissioners of Sewers at a meeting held on Tuesday, the 29th ult.:—

To the Honorable the Commissioners of Sewers of the City of London.

We whose names are hereunto subscribed of your Streets Committee, to whom on the 26th of February last it was referred to advertise for tenders for electric lighting, based upon the conditions then approved, do certify that in the first place we instructed the engineer and solicitor, with Mr. Preece, the electrician, to prepare the necessary form of tender and specification.

This having been done, and advertisements issued, tenders were received on the 10th of May from the undermentioned companies, viz.:—

The Anglo-American Brush Electric Light Corporation for the West and Central Districts.

The House-to-House Electric Light Supply Company for the Eastern District.

The Metropolitan Electric Supply Company for the Western District.

The Laing, Wharton and Down Construction Syndicate (East District).

The London Electric Supply Company (all three districts).

These were referred to the engineer and solicitor for consideration, with power to consult Mr. Preece thereupon, and the engineer, in conjunction with Mr. Preece, prepared an abstract of the said tenders.

In the meantime we received a copy of Major Marindin's report to the Board of Trade on the various applications for Provisional Orders and Licenses under the Electric Lighting Act, in which he says in regard to the City:—"The Commissioners of Sewers, acting for the Corporation, are endeavouring to obtain tenders for the lighting of the city; but I see no reason why the principle that all such lighting should be done under statutory powers and obligations should be departed from in their case, and the Commissioners have since received notices from the

Anglo-American Brush Electric Light Corporation,
Metropolitan Electric Supply Company,
London Electric Supply Company,
The Laing, Wharton and Down Construction Syndicate,

that they will in the next Session apply for Provisional Orders to supply electricity within the City of London."

We have also had before us a Model form of Provisional Order, prepared under authority of the Board of Trade.

On carefully considering the tenders sent in, together with the suggestions of the Corporation in regard to conditions, it was found that the tender of the Anglo-American Brush Company was the only one practically in accordance with the specification, and under the advice of Mr. Preece we instructed the officers to negotiate further with the Metropolitan Electric Supply Company and the London Electric Supply Company with a view to arrange similar terms with them.

This has since been done, with the result that they have severally modified the terms of their tenders, so as to bring them into uniformity with that of the Anglo-American Brush Company, and broadly all these three Companies now agree to accept the terms of the Provisional Orders now sanctioned by the House of Commons.

The prices per annum per arc lamp are as follows:—

London Electric Supply Company.....	£24	3	10
Metropolitan Electric Supply Company ...	26	0	0
Anglo-American Brush Corporation.....	26	0	0

But the London Electric Supply Company propose to extinguish half the lamps at midnight.

After full consideration, we beg to recommend that the tenders of the said three companies be provisionally accepted subject to their agreeing to enter into a contract for 21 years, determinable by either party at the end of 7 or 14 years, and the London Electric Supply Company waiving the condition as to extinguishing half the lamps at midnight.

That the three districts into which the City is divided for this purpose be allotted as follows, viz.:—

No. 1, West. To the Metropolitan Electric Supply Company.
No. 2, Central. Anglo-American Brush Corporation.
No. 3, East. London Electric Supply Company.

To light the main thoroughfares by means of 395 arc lamps will cost £10,024, in place of 1,730 gas lamps now costing £5,530 per annum, but whilst the price will not be double that of gas the amount of light will be many times greater.

DISCUSSION.

Mr. DAY (the Chairman), in moving the adoption of the report, said the cost of the electric light was of course greater than gas, but the result would be that the City would receive something like from four to six times as much light as now. One company proposed to turn out every other light at midnight, and Mr. Preece said there would then be as much light as with gas. There were a few minor points which it would be necessary for the engineer and Mr. Preece to arrange.

Mr. GREENWOOD asked which company it was that required half the lights to be turned out?

Mr. DAY: The Electric Supply Company.

Mr. MANNERS: That was not agreed to.

Mr. C. T. HARRIS did not think they were prepared to settle so important a matter that day. He moved that the report be printed and circulated, and its consideration adjourned.

Mr. GREENWOOD seconded the amendment. It would cost double the money, and the ratepayers should have an opportunity of expressing their opinions on it.

Mr. SHAW said there were occasions when it might be desirable to postpone the consideration of a question, but in this case he had not heard a single argument to justify their doing so. On February 19th the question was brought up, and a special Court was called on the 26th to take into account the whole matter. It was discussed at very considerable length and they had every information. A large time was occupied in preparing advertisements in such a form as would meet the desires of Mr. Preece and carry out the wishes of the Commission. To say that they must discuss this *de novo* was childish. The conditions agreed to by the Commission were the conditions on which the advertisements had been based, and on which these several companies were willing to do the work.

Mr. INNES said he was the last person to desire to stop electric lighting in the City, but he was not sure that all the companies would come in under the specifications which had been voted by the Commission. He was induced to think that some of the companies wanted a modification.

The CHAIRMAN voted, on division, against the amendment, the result being a tie—for the amendment, 22; against it, 22.

The CHAIRMAN gave his casting vote against the amendment, which was therefore lost.

Mr. INNES asked the Solicitor whether there was any alteration of any kind in the report between the terms agreed to by the Commission and the terms of the companies.

The SOLICITOR said he was not quite aware of the terms Mr. Preece had arranged. As a matter of fact, all the tenders differed from the original conditions.

Mr. INNES: Then in view of that statement I move that the debate be adjourned.

This was carried on a division by 24 to 20.

BY W. OSTWALD AND W. NERNST.

(Concluded from page 301.)

The authors next go on to consider the subject from a theoretical point of view, and arrive at the conclusion that the above hypothesis would not only be in contradiction with the experimental results referred to by Clausius, but would lead to results inconsistent with the fundamental principles of Thermodynamics. They then reason as follows:—Imagine a metallic conductor in the form of a very thin horizontal circular disc mounted upon a vertical axis passing through its centre, and about which it can be made to rotate. Let one of the plates of a condenser be placed just above a portion of the disc and the other plate just below it, and let a definite difference of potential be maintained between the two plates. If the disc is then made to rotate, no work will be done in virtue of the electrification of the condenser, provided the motion is so slow that the development of heat in the disc, due to the motion of the induced charge within it, may be neglected. Now suppose the metal disc to be replaced by an electrolyte of the same form. Then if the ordinary law of electrostatic distribution holds for electrolytic conductors, the electrolyte also will absorb no work. On the assumption that when an electrolyte is charged electrostatically, work is absorbed in separating the ions, it can only be done at the expense of the heat of the surrounding fluid, so that the portion of the electrolyte which lies between the plates of the condenser must be cooled. On passing out of the field of electrical action, the ions will again unite and will then give out the same amount of heat. Thus we should have an apparatus capable, without expenditure of work, of establishing a continuing difference of temperature, a result in contradiction with the second law of Thermodynamics. The authors then ask us to imagine a metallic sphere surrounded by a concentric sphere of liquid electrolyte, and separated from it by an insulated layer of air. This metal sphere is to be supposed capable of being charged positively or negatively at will, while the hollow liquid sphere of electrolyte must be imagined to be connected with a sufficient mass of the same solution for its potential not to be sensibly affected by charging the metallic sphere. If a definite charge is then given to the metallic sphere an equal and opposite charge will be induced upon the surface of the hollow sphere, assuming as before that the electricity carried by the free ions distributes itself according to the ordinary law of electrostatics. It is easy to test this reasoning by experiment, for if there is not a charge upon the inner surface of the outer sphere equal and opposite to that of the metallic one, the hollow electrolytic sphere will not screen external space from the electrical action of the charged sphere. To determine whether a layer of electrolytic liquid has such a screening effect or not, the authors made the following experiment:—A zinc case was constructed upon a wooden framework within which was placed a small influence machine. In one of the vertical sides of the case a circular opening was cut and filled up with filter paper soaked in hydrochloric acid and pressed between the plass plates. On either side of these plates were placed metal discs, 25 centimetres in radius. The disc within the case was then connected with the terminals of the influence machine, and the other with a Hankel gold-leaf electroscope. The other terminal of the machine was connected to the case, which was put in connection with the earth. The electrolytic layer was earth connected by means of an unpolarisable electrode, consisting of mercury covered with a solution of mercuric chloride. It was then found, as was anticipated, that when the machine was worked and the connections with its terminals interchanged no effect was produced upon the electroscope, although the sensitiveness was such that if the screening had been imperfect by one part in ten thousand an effect would have been observable. The hypothesis that the separation of the ions only take place in consequence of the electrification is therefore untenable, and we are entitled to regard the system as determined by two variables, namely, the absolute temperature T and the electrostatic charge E of the metallic sphere, provided that the change in E is not sufficiently rapid to give rise to changes in the concentration of the liquid, and that the development of heat due to the motion of the electricity is negligible. Let a quantity Q of heat be added to the system and be expended in increasing the internal energy U and in doing internal work, then

$$dQ = dU + a\,E\,dE \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where a is a constant depending upon the dimensions of the system. In the special case considered here its value is $\frac{D}{R(R+D)}$ where R is the radius of the metallic sphere and D the thickness of the layer of air between it and the hollow sphere. The work done in increasing the charge from E to E^1 will be, according to Clausius (Poggendorff's *Annalen*, Vol. LXXXVI., p. 337), $\frac{1}{2}(E-E^1)^2 a$. Equation (1) may be written in the form

$$\frac{dQ}{T} = \frac{1}{T}\frac{dU}{dT}dT + \frac{1}{T}\left(\frac{dU}{dE} + a\,E\right)dE \quad . \quad . \quad . \quad (2)$$

And according to the second law of Thermo-dynamics $\frac{dQ}{T} = dS$ is a one-valued function of T and E, and therefore

$$\frac{dS}{dT} = \frac{1}{T}\frac{dU}{dT}; \quad \frac{dS}{dE} = \frac{1}{T}\left(\frac{dU}{dE} + a\,E\right).$$

Differentiating these two equations with respect to E and T we obtain :—

$$\frac{d^2S}{dT\,dE} = \frac{1}{T}\frac{d^2U}{dT\,dE};$$

$$\frac{d^2S}{dT\,dE} = -\frac{1}{T^2}\left(\frac{dU}{dE} + a\,E\right) + \frac{1}{T}\frac{d^2U}{dT\,dE}.$$

Again, $0 = \frac{dU}{dE} + a\,E$, and substituting in equation (2) we find $dQ = \frac{dU}{dT}dT$, or if we suppose the process to take place isothermally, $dQ = 0$; that is to say, no work would be required to separate the molecules into their ions, and we may conclude generally that the ions which participate in the conduction of the current are in a state of free motion. The requirements of the mechanical theory of heat thus lead to the hypothesis of Arrhenius. The authors then restate as follows the theory of electrolysis from their point of view. Suppose we have an electrolyte having the potentials at two surfaces within it maintained at the potentials $+v$ and $-v$. The first effect produced, in accordance with Ohm's Law, will then be an electrostatic distribution of potential, varying from $+v$ to $-v$ upon the surface of the conductor, consisting, as before pointed out, in a distribution of positive and negative ions respectively over the surface. There will therefore be, as Kirchhoff pointed out in the case of metallic conductors, a force acting upon the electric charges in the portion of liquid included between the two surfaces in such a direction as to drive the positive charges one way and the negative charges the other. In electrolytes, however, the charges are united to the ions, and the forces upon the two being equal will set them in motion with a velocity which will be inversely proportional to the frictional resistance to which they are subject. The quantity of electricity transferred in unit time will, therefore, be proportional—

1. To the difference of potential.
2. To the number of free ions.
3. To the sum of the migration velocities of the ions.

This is the essential condition of electrolytic conduction, and is exemplified in the case of a closed electrolytic conductor in motion in a uniform magnetic field, when the work done against electrodynamic forces will appear in the form of heat in the conductor. In the case of a system consisting of both metallic and electrolytic conductors, the electricity on reaching one of the metallic surfaces will pass on in some manner which is as yet unknown to us, but is probably not very dissimilar to electrolytic conduction, while the ions will remain behind in the electrolyte, and being incapable, after losing their charges, of separate existence, will either unite with other ions, or will decompose the solution and form fresh compounds. The passage of the electricity from the ions to a metallic conductor requires a certain minimum difference of potential. As long as this is not attained, the system consisting of metal and electrolyte will act like a condenser, similarly charged atoms accumulating at a given surface of separation, which would give rise to an opposite electrification on the inner surface of the metal, and allow electricity similar to that on the ions to flow away. Now we know that the smallest E.M.F. is capable of starting an electrolytic current, but this will only continue until the condenser is charged, and will cease when convection ceases to take place. These conditions are fulfilled at each pair of separating surfaces of the metal and electrolyte, and determine the polarisation. The theory then leads to the known experimental result that as the E.M.F. of the primary current increases, the E.M.F. of polarisation will also increase to a certain maximum value, namely, until the electrical double layer is completely formed. When the primary E.M.F. is further increased a transference of electricity will take place from the ions to the metals, corresponding to the spark discharge of a condenser. If the metallic surfaces or electrodes are metallically connected, while in the stage of polarisation, so as to equalise their potentials, there will no longer be a force acting upon the ions tending to drive them in opposite directions, and therefore they will begin to approach each other and unite again, so that the electrification accumulated on the electrodes by the condensing action will be set free and equilibrium will be established through the metallic connection.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1888, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

"THE ELECTRICAL WORLD" OF NEW YORK.

Arrangements have been made by which "THE ELECTRICAL WORLD" OF NEW YORK *can be obtained from* "THE ELECTRICIAN" *Office, 1, Salisbury-court, Fleet-street, London, E.C.*

The Rate of Subscription (payable in advance), is **£1 1s. 0d.** *per annum.*

"THE ELEKTROTECHNISCHE ZEITSCHRIFT" OF BERLIN.

"THE ELECTRICIAN" COMPANY *are also Agents for* "THE ELEKTROTECHNISCHE ZEITSCHRIFT" OF BERLIN, *published Fortnightly, and copies of this well-known Electrical Journal can be obtained at the Offices of* "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, E.C.,* **price 8d., post free, 10d.** *The Annual Subscription is* **£1. 2s. 6d.** *(post free),* PAYABLE IN ADVANCE.

Subscriptions are received by this Company for all Continental and American Electrical Journals. Subscription Rates on application to "THE PUBLISHER." *Remittance must accompany order* IN ALL CASES.

ALTERNATE CURRENT WORKING.

The discussion on Mr. MORDEY'S Paper on Alternate Current Working, read two months ago before the Institution of Electrical Engineers, has just been published in the recently issued number of the *Journal*, and as each speaker has presumably had the opportunity to revise and condense his remarks, and as we print in another place Mr. MORDEY'S reply, the present moment is a convenient one to review the discussion and endeavour to see how far the scientific horizon has been widened by the various opinions so expressed. Most of the principal speakers, from the President downwards, bore testimony to the practical worth of Mr. MORDEY'S contribution. We do not think that these remarks were merely complimentary, but that those who so spoke sincerely considered that the Paper was a valuable and practical donation to electrical knowledge. The Paper had in it all the good elements which a memoir of this character should have. It summed up very fairly existing knowledge, it stated clearly some definite views formed by the author, and, more than all, it described successful and highly important experiments on the parallel working of alternators, which were repeated again a few days later in the presence of a party of engineers and experts assembled at the works of the Brush Company. Reviewing, however, both Paper and the discussion, we cannot but feel conscious that the problems with which this Paper deals are not yet generally solved, and that we are still in the period

Digitized by Google

when notions of various kinds respecting them are fermenting in many minds, but that the process of converting these more or less nebulous ideas into sharply-cut definite conceptions and practical rules is yet incomplete. Put more definitely, what this amounts to is somewhat as follows:—Six or seven years ago, although even before that time Mr. WILDE had shown the possibility of running alternators in parallel, electrical engineers may be said to have been almost universally of opinion that alternators could not be got to work practically in parallel. Dr. HOPKINSON'S published Papers in 1883, and his experiments jointly with Prof. ADAMS in 1884, may be considered to have destroyed the merely negative opinion, and to have demonstrated that certain types of alternators could, and did under certain circumstances, work in parallel. Since that time we have had many more or less similar successful experiments effecting the same thing, not merely in the form of workshop experiments, but in the actual work of a central station. Those whose interests lie rather in the direction of the development of direct current working are very strong in the opinion that these attempts have never got beyond large scale workshop experiments, but on the other hand, we have other engineers of repute who claim, as does Mr. ZIPERNOWSKI, on behalf of Messrs. Ganz and Co., that they have alternate current machines running in parallel in a thoroughly satisfactory manner, with widely varying loads, in central stations in Rome, Livorno, Frankfort-on-Main, and Marienbad. The previous experience, however, which is well set out in Mr. MORDEY'S Paper, amply justifies the view that the general principle on which the successful running-in-parallel of alternators depends had not been previously arrived at or displayed, and that the accomplished facts had been only of the nature of demonstrations that certain types of alternators could run together, but had not established any rule for guidance as to how to go to work to construct machines which should certainly do this. This is really the important matter. The practical dynamo builder does not care two straws whether the mystery of parallel running of alternators has or has not been packed up in somebody's mathematical equations to be extricated therefrom subsequently as from a conjuror's inexhaustible bag, nor does he derive much valuable guidance from the differences of experts, some of whom consider the secret depends upon abundance of self-induction in the armature, and some of whom think it does not. The dynamo designer pondering over the present and the past, and looking to the requirements of the future, "wants to know" exactly what are the conditions to be complied with in order to construct alternators which shall successfully perform this act. And, moreover, he desires this information to come to him in the form of definite guiding scientific principles and practical rules, and not merely to be told that machines, as built by some particular firms, will run in parallel together, whilst those as built by others will not do so. Mr. MORDEY took up a perfectly definite position in his Paper in submitting the view that a perfect alternator for all and every purpose should have no resistance and no self-induction. In his reply he has laid a little more additional stress upon a point which is undoubtedly of very great importance, namely, the "stiffness" of the magnetic field, and he accuses the mathematical theory of having neglected to take this into account. If these had been merely opinions based on the special knowledge of a dynamo designer of great experience they would no doubt have been received with attention; but Mr. MORDEY has done far more than this—he has proceeded to embody them in a material form, to build alternators with strip armatures of small inductance and resistance, to place them in very strong magnetic fields, and to give the most convincing proof of the excellence of this arrangement in producing mutually controlling alternators. Some of his critics, whilst giving him all praise for his experiments, dispute the validity of the reasons which he assigns for his success. First came Dr. HOPKINSON, who decides that the alternators will best control each other when the "time-constant" or quotient of the self-induction by the resistance of the armature circuit is a definite fraction (nearly one-sixth) of the complete periodic time of the machine, and that accordingly a little self-induction in the armature is sometimes a benefit. In order to test this theory it is absolutely necessary to possess measured values of these three factors for machines which have been found to work in parallel well, or the reverse in practice, and the collated figures would be of immense assistance in proving or disproving the theory.

Mr. KAPP entreated his audience not to allow themselves to be influenced by Mr. MORDEY'S attempt to use the successful experimental facts in upsetting a well-established theory. Considering how very wide the differences of opinion on the alternator theory are, it can hardly be spoken of as "well established," or it would surely be less the subject of difference in debate than it is. Mr. KAPP claimed as proof that Mr. MORDEY'S armature was not free from self-induction, or its equivalent, the striking experiment of running in parallel the machines at 2,000 and 1,000 volt excitation respectively. At the end of the evening Sir WILLIAM THOMSON, however, gave a different view of this experiment, and his remarks, which were naturally listened to with great attention, carried, we think, conviction to the minds of those who heard them that the reaction of the armature currents upon the magnetism of the fields is at the bottom of this striking experiment. Mr. SWINBURNE joined Mr. KAPP in deprecating what he called Mr. MORDEY'S attack on existing theory; but, as we have said above, theory in the sense of an actual explanation of observed effects, or a power of predicting fresh facts, does not at present exist, and his reasons for thinking that the 2,000 and 1,000 volt experiment argues large self-induction are best disposed of by reading attentively the President's remarks.

Prof. S. P. THOMPSON touched more nearly the vital point, also briefly alluded to by Dr. FLEMING, viz., the relation of the stability of synchronisation upon the armature inductance. He did not agree with Mr. KAPP that this stability depended upon self-induction, at least in the armature itself. Prof. AYRTON contributed one valuable element to the discussion by giving the actual measurement of the self-induction of the Mordey armature in various positions *in situ*. Armed with his secohmmeter and aided by his corps of ever faithful students, he was able to so far sit in judgment on a portion of the case as to decide the armature inductance to be about one-thirtieth of a secohm. If he could carry out a large campaign against all sorts and conditions of alternators and obtain the three factors of armature resistance, inductance, and periodic time, we should have the materials in hand for some very valuable discussion. These and such-like quantitative experimental researches are the only stepping stones likely to promote real progress.

Let us look for one moment from what may be called the purely common sense point of view at the conditions which are likely to be required to be present in order that two alternators may keep step together. The machines being supposed to be initially in step and independently driven, let one of them now begin to lag behind. In order to bring it up again into step it requires to be rapidly and effectively converted into a motor—that is, the lagging machine must drop its character of current generator and take upon it the function of motor whereby it is brought up again into step and then resumes its *rôle* of current producer. Not only must there be great promptness in the assumption of the motor function the moment any sensible lag occurs, but the motor character must

Digitized by Google

be very pronounced; the machine must, as it were, transform very quickly from a good dynamo into a strong motor. In this way the very attempt at lagging is checked promptly. The machine must not dally with the danger, or linger until the lag has increased to such an extent as to reverse the sign of the electro-motive force of the lagging machine relatively to the other. The lag is to be looked upon as a sort of disease which imperils the steadiness of the mean electromotive force in the external circuit, and the machines must automatically, promptly, and vigorously apply the proper remedy. It does seem to suggest itself that a disposition so to do this requires two conditions — first, that nothing shall hinder more than necessary the reversal of the current in the armature circuit. Small time-constant is not the only element, however; we must have, secondly, a "stiff" magnetic field, or one on which the armature current produces by its reaction very little effect. The reversed armature current must be coupled with the rigid magnetic field, or else the armature has nothing as it were to pull against. The would-be mountaineer on an ice slope requires to find a strong and unyielding arm or rope to hold on to in order to recover from a slip of the foot, and the rigid magnetic field is that which the back-slipping armature grasps at in order to recover its lag. This is virtually Mr. MORDEY'S theory. It may be that subsequent knowledge will modify it, but it looks at first sight as if it would hold water. Those who differ from Mr. MORDEY, and who fight under the other banner, and think that a good deal of armature self-induction is essential to success, should now, if they can, produce measurements or facts to show that a diverse set of conditions will produce the same result. It does not follow that alternators with iron-cored armatures and having large self induction are in any way at a disadvantage. They may have a higher internal resistance, and sensibly the same relation of time-constant to periodic time, whilst possessing also the other necessary condition.

Summing up all the discussion, we may say that, although we have not yet arrived at that useful and simple generalisation of experience for wh ch we are waiting, we have yet had the ball set rolling and sufficient diversity of ideas expressed to make it evident that the chief pitfall to be avoided is haste in stereotyping our views. We should endeavour to prevent ourselves from being put in bondage to words, and by an energetic collection of experimental data endeavour to ascertain what are the practical conditions to be complied with to produce alternators which, when put together in parallel, are strongly co-phasial synchronisers. When this is done it will create no more surprise to see a battery of a dozen alternators run in parallel than it does now to see a batch of continuous current dynamos so worked. Present success is an earnest of such future achievement, and the differences of opinion which the present debate reveals will be settled once for all only in the light of such accomplished facts.

OBITUARY.

JAMES CLARKE BEY, C.M.G.

The death is announced of John Charles James Clarke Bey, C.M.G., Superintendent at Alexandria of the Egyptian Government Telegraphs. He was 43 years of age, and had been employed, says *The Times*, in the service of the telegraphs of the Khedive for many years at Zagazig, and more recently at Alexandria. In 1882, when the rebellion of Arabi Pasha occurred, he offered his services to the British Admiral, and being a good Arabic scholar and well known to the Bedouin, was employed from July 29 to September 25 upon many important secret missions in connection with the Intelligence Department. By his knowledge of telegraphy he prevented any news of the landing of the British troops at Ismailia from reaching the ears of Arabi, and he succeeded in obtaining a quantity of railway trucks and engines to convey our troops into the country. On September 13, the day of the battle of Tel-el-Kebir, when he was attached to the Indian contingent under General Macpherson, he seized the telegraph office at that place, went on to Zagazig, and there ascertained that 15,000 rebels were at Salieh with 26 guns, and that they were within an hour and a-half by train of Zagazig. As delay was now most important to the British troops, Mr. Clarke entered the telegraph office, obtained the private signals, and found out that two trains containing about 5,000 troops were waiting at Aboukebeer for the signal to come on to occupy Zagazig, and that others were getting ready. He telegraphed to Aboukebeer, "Two engines in collision at the junction, line not clear." This gave General Macpherson, who only had 70 or 80 men with him, time to send them forward and tear up part of the line. He subsequently telegraphed to the commandant of those troops to fall back. For these and similar services he obtained the war medal and clasp, the star, and was created a Companion of the Order of St. Michael and St. George; and from the Khedive he received the Fourth Class of the Imperial Order of the Medjidieh. In 1886 he was created a Bey.

ALTERNATE CURRENT WORKING.*

The following is the full text of Mr. Mordey's reply to the discussion on his Paper on "Alternate Current Working," the authorised abstract of which we published in our issue of June 7th:—

I wish in the first place to express my thanks for the very kind way in which you have received this Paper. The criticisms have, in some cases, been answered by other speakers. The remaining points in regard to which the speakers are not in accord with me I must deal with so far as I can in the time at my disposal, but I need not occupy time by referring to other matters.

Dr. Hopkinson's statements on electrical subjects are always received, not only with great respect, but as being usually correct and final. I join in the respect, but venture to question the correctness in this instance. If Dr. Hopkinson would be better satisfied by my stating that the most perfect alternator conceivable is one which has an indefinitely small self-induction and resistance, I am quite prepared to express my meaning in that way. I was acquainted with the general practical results, as regards parallel working, brought before us in 1884 by him, but, for reasons which will be understood, I did not derive any assistance from his theory, nor do I now agree that that theory "is sufficient to predict all the results obtained." I cannot fully argue this point, but must ask Dr. Hopkinson if he will kindly look into it again, for I am strongly of opinion that he will find it is not as complete as appears to be supposed. I am the more convinced of the correctness of my explanation by the measurements of the self-induction of my armature by Prof. Ayrton's assistants, using the new Ayrton and Perry instruments, and by the statement made by Prof. Ayrton that the time-constant, or ratio of the self-induction to the resistance, was about the same in my machine and in that of an alternator of another maker, which latter machine only exhibited very feeble synchronising properties when attempts were made to run two of them in parallel.

The point where mathematical treatment of the subject appears to have failed is that it has not taken sufficient account of the "stiffness" of the field. This is at once apparent when this measurement of the self-induction of one of my machines is referred to, from which it will be seen that the self-induction was practically the same whether any impressed field existed or not. Manifestly, with no impressed field, the controlling power of the machine would be quite inconsiderable, although the values of self-induction and resistance—upon which Dr. Hopkinson relies—would be the same then as when the machine was working with a strong impressed field, and under the conditions giving the maximum generating and controlling power. Hence it is evident that a theory which only takes cognisance of self-induction and resistance must be altogether illusory.

There are several reasons for the view that his theory is incomcomplete. His paper has been before the world for several years, and has been often studied, but neither its author (who has been engaged on the subject) nor anyone else has ever based any practical advance on it. Working parallel has been recently considered,

* From the *Journal* of the Institution of Electrical Engineers.

Digitized by Google

as a question of great urgency and importance, before this Institution and elsewhere, and there have been abundant opportunities for bringing forward any useful information; but the whole subject was misunderstood, and Dr. Hopkinson, who has been a witness of the struggles that on all sides were being made towards a better understanding of it, has remained silent. I am sure that nothing would be more unlike him than to let the whole industry suffer for want of a little clear and definite information, if he had been able to give that information. Dr. Hopkinson even took part in the discussion on Mr. Kapp's Paper a few weeks ago, and threw no light on this question, thus tacitly subscribing to the current views.

It would be easy to find several other instances, besides those mentioned in the brief enumeration in my Paper, to show that the views generally held were entirely misleading and incorrect. For example, Mr. Swinburne alludes to* Dr. Hopkinson's mathematical treatment, and says that he has put the matter into English in his book;† and I find in that (recently written) book it is stated (on p. 151) that there are no alternate-current motors. But nothing less than the actual words can show how completely misleading this theory was. Mr. Swinburne proceeded, in the book in question: "It seems generally to be assumed that the only difficulty with alternating-currents motors is to start them. It seems probable, however, that there will be very great difficulty in designing a motor which will work with reasonable efficiency and varying load. An alternating- is a widely different thing from a direct-current motor."

Having seen all these statements disproved—having seen a 50 horse-power synchronising motor running with high efficiency under varying load, and designed on the lines of a direct-current motor—Mr. Swinburne now comes forward and says:‡ "I see nothing in Mr. Mordey's interesting experiments which conflicts with the recognised theory; in fact, *the position of synchronous motors is not altered*"—the italics are mine. Truly the Hopkinson theory, as rendered into English, must be capable of infinite elasticity.

Then again, only a few months ago, Mr. Swinburne, who had assimilated this theory, stated§ that such machines as mine would not run in parallel at all, and he described an "induction coupler" which he had devised for the purpose of making them so run by inserting self-induction. That device is a very good illustration of the results of the old theories. I may mention that when I was labouring in the slough of those old theories I independently devised that identical arrangement, which is one quite in accord with the requirements of those theories, so far as I was able to understand them; and having entirely failed to get two ironless alternators of a well-known type to work parallel in their simple condition, I tried that "induction coupler," without any improvement in the result. That was, in fact, one of the experiments that opened my eyes to the whole fallacy. It helped me to see that anything that prevented the instantaneous passage of the necessary correcting current must inevitably tend to prevent synchronous action.

Referring to Prof. Adams's criticism, I may say that I was fully aware of his experiments at the South Foreland Lighthouse, and referred to them. Prof. Adams considers those experiments as conclusively establishing Dr. Hopkinson's theory. I need not again consider them in that connection, but would only say that the motor effects obtained were not powerful, and that they have not been taken as forming a basis for practical construction. Indeed, they have remained on record as the not very high tide-mark beyond which no substantial advance was found practicable until machines having very different qualities were developed. It would cause me no surprise to find that the South Foreland experiments succeeded from quite different causes than those imagined by Prof. Adams. It is not at all clear that any of the advocates of Dr. Hopkinson's theory really understood what that theory is. It seems to cover a multitude of quite opposite interpretations, and resembles some of the Hebrew prophecies in its comprehensive applicability to occurrences—after the event. Prof. Adams, I am afraid, rather supposes that I make some sort of claim to having introduced parallel working. The object of the first portion of my Paper was rather to state what lines I thought should be followed in order to obtain the best results, and to show that on those lines complete success could be attained at a time when, in spite of Prof. Adams's well-known and valuable Paper, considerable and well-founded doubt existed as to the commercial possibility of parallel working. In one respect, however, I am quite unable to follow Prof. Adams, and that is in some of his analogies between alternators working parallel and tuning-forks vibrating in unison. He says that I gave the octave when I had one machine working at 1,000 volts and the other at 2,000 volts, both being at the same speed, and he suggests that I should give the double octave, and various other ratios. Now I fail to see that there is any true analogy between various rates of sound vibration produced by tuning-forks and corresponding ratios of electrical pressure. It would be just as correct to say that a steam boiler with a pressure 120lb. on the square inch was giving the octave of another boiler working at 60lb.

As to the very different problem of running alternators parallel when the alternations are an octave of one another—a possibility that is also put forward by Prof. Adams, and which has been mentioned to me by Mr. Sumpner and others—I can only say that I have not tried it, partly because it does not hold out any promise of a useful result if successful, and partly because I feel pretty sure it would not succeed, except with machines having so much self-induction as to render them unsuitable for practical purposes. A little consideration will, I think, show that this must be the case.

Prof. Adams refers to the loud humming noise made by my alternators when they were connected parallel while out of phase as "very sufficient evidence of very considerable self-induction, in consequence of which the speed of one machine is suddenly increased, and of the other as suddenly diminished." This noise is really a proof of the contrary. It is caused by the enormous rush of current which the comparative absence of self-induction renders possible, and this momentary rush puts the machines in phase with a jerk. As bearing on this point, I may mention that some machines that are said to have large self-induction do not make this noise under the same circumstances. Their self-induction prevents any such rush of current, and, according to my view, also prevents their working parallel. Although dissenting from my explanation, this rush of current is recognised by Mr. Swinburne as a proof of absence of self-induction.

It is interesting and important to consider another action arising out of this matter. In several machines—some with and some without iron—the self-induction is so serious that it does as well to short-circuit armature coils as to cut them out when it is desired to reduce the potential difference at the terminals. In fact, these machines cannot be injured by accidental or intentional short-circuits. They obtain this advantage, however, at the cost of every other good quality. The rush of current, the effect of which Prof. Adams noticed, but misunderstood, in my machine, could not take place with such high self-induction machines. They could be put into connection when out of phase, and would simply choke back the current which attempted to put them into step.

I think there is no real difference of opinion between Major Cardew and myself on the subject of safeguards. I quite agree with him that the two contacts *a* and *b* may be "ready waiting" for a person to make the other two contacts and so receive a shock. It is to prevent the possibility of this that I so strongly recommend earthing. It is an absolute safeguard, costs nothing, and does not cause interference with the telegraph or telephone service. I cannot admit that it increases fire risks. I think it lessens them, because it makes it certain that a faulty transformer or house circuit cannot remain on. The safety fuse on an earthed circuit instantly cuts off a faulty house, and so prevents that gradual accumulation of unsound or actually defective places that, without some such safeguard, would soon render a large supply service unworkable. As to the supposed excessive strain on a 100-volt circuit if it is earthed, that does not exist in practice. The secondary is earthed in the middle, so that the strain is really only 50 volts; and an installation that will not stand that strain is radically bad and ought not to be allowed anywhere. The great advantage of earthing is that it secures safety, protects the customer against bad work and leakage through his meter, and protects the system against the presence of rotten installations. If the fire offices do not see before long that earthing does not increase fire risks, I shall be greatly surprised.

One or two points in Dr. Fleming's remarks require some reply from me. His suggestion to account for the behaviour of transformers with different periodicities is, I think, very pretty and very ingenious. At first I could not fully accept it, as the greater penetration of the eddy currents into the iron at a low periodicity seemed to be an effect that would not be likely to be felt with very thin conductors such as the laminated iron; but I now see that the currents in the laminations, although very close together and insulated from each other, can act on one another and produce the "virtual resistance" effect.

Prof. Fleming's objection to my substitution of the word "magnetisation" for "induction" is not a very strong one. I have only to say that I think "induction" would not be a good word even if it had not already been secured for a dozen other purposes. Some limit should be placed to the multiplication of meanings given to this one word, which, after all, is not an electric or magnetic word at all.

Mr. Kapp has latterly given much attention to this subject of alternate-current working, and understands its difficulties. On this account and also because I was obliged to strongly oppose some of his views, I highly appreciate his kind remarks about the Paper. He accepts all my facts, but rejects my interpretation. He will, I feel sure, accept them both on further consideration.

The experiment of which he suggests an explanation, which is in some respects similar to the explanation proposed by Sir William

* *The Electrician*, June 14th, 1889, p. 154.
† "Practical Electrical Measurement."
‡ *The Electrician*, June 14th, 1889.
§ *Journal*, Vol. XVII., p. 401.

Digitized by Google

Thomson, is no doubt a very interesting one. It is a case not very likely to occur in practice, but deserves attention. I do not, however, quite agree with Mr. Kapp and Sir William Thomson. I wish their explanations were more convincing, and were not so much opposed to Prof. Ayrton's measurements of the self-induction with different relative positions of armature and field, and with various field strengths, which showed that the actual conditions are exactly the reverse of those relied upon in Mr. Kapp's supposition.

I think that in any case the actual magnetising or demagnetising action exerted by the armature on the field magnet must be small, partly for the reason, pointed out by Prof. Silvanus Thompson, that there was not time in a half-period for the solid iron to undergo any change, and partly because the armature is purposely made so as to exert as small an effect of that kind as possible. The machine consists of a very powerful electro-magnet, the field; and a very weak electro-magnet, the armature Even if coils similar to the armature coils were wound on the extremities of the polar horns, and had a direct current sent through them equal to the maximum working alternate current, they would not produce a very powerful effect on the field.

One of the difficulties met with in considering this question is that there is no means of knowing which machine was generator and which motor. This depends, of course, upon the relative power of the engines. It is quite possible that the lower E.M.F. machine was acting as the generator.

I can only say that I will take the first opportunity of acting on Sir William Thomson's suggestion as to testing the supposed changes of magnetisation, and hope thus to be able to settle this question.

Mr. Swinburne challenges my conclusions on several points with his usual vigour, and I very willingly take up the gauntlet. I have already alluded to some remarks of his which place him in the honourable light of an interpreter of Dr. Hopkinson's mathematics. The position is one that requires great powers of endurance and considerable courage.

Mr. Swinburne says that "electrical engineers do not realise what is wanted in parallel running." I accept this candid statement as, at any rate, quite correctly describing his attitude in the matter; and am therefore, of course, prepared to find that he disagrees with most of my views.

He commences by stating that so far from the motor being kept in step because its self-induction was small, that, if there were no self-induction, the generator would have no control at all over the motor.

This is an instance of a very common mistake—that of supposing that if there is practically no self-induction there can be no generating or motive capability. The exact contrary is the case, as I tried to explain in the Paper when I expressed the view that "a perfect alternator for any and every purpose should have no resistance and no self-induction." Of course this condition is unattainable in practice. It is a mere expression of the direction in which it appeared desirable to advance; and, as I have already said, I am prepared to put it that the most perfect alternator conceivable is one which has an indefinitely small self-induction and resistance. This idea that the generating or controlling power is connected directly with the self-induction is clearly upset by the fact, shown by Professor Ayrton's experiments, that the self-induction is not sensibly altered by variations of the field strength or position. I need scarcely repeat that the generating or controlling power depends almost entirely on the field strength and position relatively to the armature.

But Mr. Swinburne sticks to the ordinary fallacy, and says—or implies—that such a machine would not act at all either as generator or motor, and reproaches me for attacking existing theories without giving one of my own to take their place. Even that course would have been quite justifiable if I had found the existing theory bad. But I have given a theory. I have said what I thought a perfect generator or motor should be, and have attempted to explain the *rationale* of the action of two such machines when controlling each other. Let me take a case. The armature of my machine has a certain resistance and a certain self-induction. These qualities are unfortunately unavoidable, but I made the machine as good as I possibly could by reducing them both. This was done by the use of a strong and "stiff" field. Need I explain that, if the properties of iron had permitted it, I should have been able so to increase the field as to allow of a proportionate reduction of the resistance and of the self-induction of the armature. And if I could have got an indefinitely strong field I should have reduced the armature resistance and self-induction also indefinitely. Then I should have the "perfect alternators" that I alluded to working as generators or as motors, singly or parallel.

But Mr. Swinburne, bearing out his opening statement, implies that such machines would not work at all.

Then, again, speaking generally, he says: "To make them run parallel commercially needs a large corrective tendency. This can only be got by making the machines so that the maximum current is not at the same time as the maximum E.M.F." This is exactly the opposite of the actually best conditions. Of course they need a large corrective tendency and great stability, as Dr. Fleming says. I urged this strongly in my Paper. Inverting Mr. Swinburne's statement—which really means that the machines must have large self-induction—I say this large corrective tendency can only be got to its fullest extent by making the machines so that the maximum current is at the same time as the maximum E.M.F., at any rate when working on an inductionless circuit. Mr. Swinburne quite correctly interprets the restriction imposed by the conditions he thinks best when he says "that the machines must be made larger to give a given output. They must also be somewhat less efficient." The whole object of the first section of my Paper was to show that such views were both practically and theoretically wrong, and I am surprised that a literal restatement of them should now be put forward.

The best practicable alternator for any and every purpose should have the lowest practicable resistance and self-induction. It will not be larger for a given output or less efficient. It will not have its maximum current at a different time from its maximum E.M.F., and it will exert a large corrective tendency in the most powerful and unhesitating manner, and will maintain synchronism with the least difference of time-phase between any two machines. Such are the views to which I am driven by the logic of facts. On one point I agree with Mr. Swinburne—that if a large corrective margin is required, the internal loss must be large; but even here we do not fully agree. With the old theories the corrective margin was out of all proportion to the effect required to be produced. By the sudden and strong action I obtain by departing as far as possible from the old theories I get this large corrective margin of power by a small margin in the capacity of the machine. It is obviously unwise, however, to attempt to run machines parallel when they require to exert a large controlling power. My experiments showed that they could exert this power; but the driving plant that requires large control is not suitable for parallel working.

Mr. Swinburne's calculations on the efficiency and dimensions of transformers are, I am sure, very interesting; but I scarcely think we are yet in a position to settle these matters entirely on paper. There are so many variables, and there is so little actual knowledge of the laws governing the heating by eddies and by hysteresis in transformers, that it is probably best to rely mainly on experiment for the present. Thus Prof. Ewing says in his letter: "We cannot be sure that the loss by hysteresis is proportional to speed, especially when the speed is "high;" and my experiments on armature cores support this view. Mr. Swinburne, however, is sufficiently sure on this and all the other points to rely upon his calculations for transformers working under widely different conditions. I admire his courage, but advise him to be prepared for disappointments when the transformers are constructed. I cannot at all agree, either, that the eddies in the iron are negligible, in spite of any calculations showing them to be inappreciable. It will be found that my tests bear out very closely the results as regards loss that are known to be obtained in low-period direct-current machines. Those experiments confirm, as regards hysteresis, the results of Ewing and Hopkinson; and as to the eddies it is open to anyone to check them by experiment or by reference to any reliable tests. I would, however, point out that in the celebrated Paper of the Drs. Hopkinson on "Dynamo-Electric Machinery,"* one of the two power readings which are available for this purpose is wrong, the total loss of power being given as less than the calculated hysteresis loss. I have pointed out this discrepancy to Dr. Hopkinson, and find that he is aware of it. It was no doubt an incorrect reading.

Prof. Silvanus Thompson and Prof. Forbes ask for information as to the governing of the engines driving the two alternators in the experiments. Those engines were not governed automatically at all; they were simply controlled by hand. Of course, if they had been well governed automatically, the tests would have been much less severe. As it was, it was left to the engine driver to give each engine as much steam as he thought was necessary. In such a case, if one engine is more powerful than another the power of mutual control is severely tested; if the engines are working under similar conditions then the corrective margin is not required to be large. The utmost strain is put on the arrangement when, as was done in the experiments, steam is entirely shut off one engine.

I trust Prof. Thompson will continue his very interesting experiments on the seat of the back E.M.F. in arcs. The subject requires investigation. The method used will probably yield useful results as regards a comparison between direct and alternate-current arcs. There is one point to which I wish to draw Prof. Thompson's attention, and that is whether there is in an A.C. arc an effect of the opposing E.M.F. in producing a displacement of the current phase. I suppose it may be taken as proved that the arc has an E.M.F. as well as a resistance; and with a rapidly alternating current it seems possible that this may produce a lag, and may act in that respect something like electro-magnetic self-induction. Such an effect may perhaps also be found in A.C. electrolysis. I note Prof. Thomp-

* *Phil. Trans.*, Part I., 1886.

Digitized by Google

son's criticism of my statement that in the characteristic the drop is partly due to resistance and partly to self-induction. He does not say that I am wrong. Several effects are produced by the currents—eddy and useful—generated by motion, and it is, I think, allowable to describe the net result on the characteristic as due to self-induction.

I have already referred to Prof. Thompson's expression of doubt as to whether there is time in a half-period for the large mass of iron in the polar horns to become magnetised. He is probably quite right, but I have had no opportunity of settling the point. If there is any effect it will probably be almost a steady one, as pointed out by Sir William Thomson ; that is to say, the iron will not follow the varying impressed magnetising force, but will take up an average state, depending upon the current and the relative position of armature and field.

Prof. Ayrton, in his opening words, appears to ally himself with the views that I have sought to upset ; but I have to thank him for having contributed an account of experiments which, perhaps more than anything I can say, tend to support my contention. He referred to the method of testing transformers that I suggested. That method may be safely used, except with a very inefficient transformer.

As to the curves of temperature, I can only say that I have no reason to doubt the accuracy of the tests, which were most carefully carried out.

Prof. Forbes pointed out that it is wrong to suppose there are only two means of distributing alternate currents. I quite agree with him ; but although I have dwelt at some length on the subject of working parallel, I do not think that method is suitable for all cases. It is a great convenience, and in a properly designed station can always be adopted ; but where, either from the design of the machines or from the character of the engines, a large corrective margin is necessary, then it may be better to work singly, putting such of the mains in parallel on one machine as may be convenient.

If the alternators are suitable for parallel work, then the different mains may be run parallel from a common or omnibus pair of terminal bars, each main being fed through a safety fuse, in order to prevent more than local extinction in case of a short-circuit.

With regard to Mr. Zipernowski's communication, I am sorry he should think the statements I made about working his alternators parallel are erroneous. Those statements are substantially quotations from his own writings. He objects to a passage in my Paper in which I said that his reason for working at the very low periodicity of 42 was to enable him to run the machines parallel. My authority was his own letter, published a few days before my paper.* In this letter—to quote it more fully—he said : "The relatively low number of alternations (5,000 per minute), which we have chosen on principle. . . that we by this means are enabled to couple our dynamos in parallel is not a secondary result, but just the end we were aiming at." Mr. Zipernowski now writes : "We state that we have not reduced the periodicity because of the coupling in parallel."

I must leave these two opposed statements to speak for themselves.

The other statement which Mr. Zipernowski questions is that the magnetic flux in the field ought to be constant, and I am blamed for not giving my reasons for this statement. I did not go into the matter very fully, as it seemed unnecessary ; but when I said that want of constancy "necessarily led to losses in the field, the lamination of which in the Zipernowski machine showing that such losses must be serious," I am sure I sufficiently indicated the nature of the waste which occurs under the conditions referred to.

I am glad to have elicited Mr. Zipernowski's remarks about the Ganz alternate-current motor, and shall look forward to seeing an actual description of that apparatus. The publications on that subject, to which my attention is called, are remarkable for the small amount of definite information they contain. I can learn nothing from them. We are not told anything at all about the form, mode of action, or principle of the machine. There are no doubt good and sufficient reasons for this reticence.

Of Mr. Fricker's contribution I need only say that it is a very clear statement, with which I wholly agree.

* *The Electrician*, May 10th, 1889.

Cape of Good Hope Telegraph Statistics.—The total number of telegraph offices worked by the several administrations of South Africa was, at the close of the year, as under :—Cape of Good Hope Department offices, 130 ; Railway offices, 93—total 223 ; Natal, 51 ; Bechuanaland, 5 ; Orange Free State, 20 ; South African Republic, 20—grand total 319, being an increase of 21 new offices. The result of the alterations made is an increase for 1888 of 29¼ miles new line and 605¼ miles new wire.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 20, 1889.

The leading topic of interest in electrical circles in this city during the past week or two has been the investigation that is being conducted by the State as to whether electrical execution is a "cruel and unusual" form of punishment, and whether the murderer now awaiting death should be subjected to it. The inquiry has developed an extraordinary difference of opinion on the subject of whether death by electricity is a sure thing or not, and whether, being sure, it is not open to objection on other grounds. In my last letter I touched on some of the points raised, and may now add that, after all is said and done, the desirability of electrical execution remains as doubtful as ever. It will be remembered that the law was passed without any elaborate or exhaustive inquiry as to the death-dealing nature of electrical currents, and that the main evidence now urged in support of it is that given by the experiments with dogs, conducted at Columbia College by Mr. Harold P. Brown, and subsequently at the Edison Laboratory. Horses and calves, as well as dogs, were submitted to the continuous and the alternating current ; but, of course, although they were killed, the fact that human beings could and would be killed in the same way was purely a matter of inference and conjecture. It cannot be said, moreover, that the experience at the dog-killing experiments was altogether of the most agreeable nature. Commissioner Gibbens, of the Subway Board, who was present, said before the referee this week, "It was one of the most frightful scenes I have ever witnessed. The dogs writhed and squirmed, and gave vent to their agony in howls and piteous wails, until at length exhausted, they fell upon the floor of the cage, worn out with their sufferings." Mr. Gibbens mentioned that his colleague, Mr. Moss, could not stand the sight, but had to retire, as, by the way, did other gentlemen, who were disgusted and sickened with the spectacle. During the present week there has been a great deal said before the referee as to the nature and quality of human resistance, and the effect of the electric current, and with this question—quite a difficult and unsettled one—has been complicated another, namely, how far a man's nerve, courage, or will-power may be able to modify or neutralise the electrical effects. From the way the newspapers are discussing the evidence that has been presented, it is evident that there is a weakening in the sentiment that favours electrical execution, and hence it begins to appear possible that we may be spared from seeing electricity applied to such degrading purposes. It is interesting to note incidentally how the question of the relative safety of the continuous and the alternating current keeps cropping up throughout the inquiry, so that one wonders sometimes as to whether the point at issue is, shall the criminal be killed electrically or shall the alternating current be admitted to general use in the same way as the continuous, arc, and incandescent current?

An interesting system of storage battery development has been brought to the notice of the electrical public this week by the Mutual Electric Manufacturing Company of Brooklyn. This system has been worked out in the "City of Churches" by Mr. E. R. Knowles, who, although a young electrician, is old enough in the art, his first experience dating back to some very interesting associations with Mr. Sawyer, the eccentric genius who figured so prominently at one time as Mr. Edison's active rival in the development of the incandescent lamp. Mr. Knowles' attention has been directed to the problem of utilising arc circuits and apparatus in the daytime. As you are well aware, incandescent stations have now pretty well reached the solution of the difficulty of running throughout the twenty-four hours by the development of power business, hundreds and thousands of motors now being operated on their circuits during the hours of daylight and supplementing the income of the companies in a very satisfactory way. For obvious reasons the introduction of motors on arc circuits has not gone by any means as far, and there are, moreover, a large number of electric plants situated in places where there is no demand for electrical power during the day. This being the case, Mr.

Digitized by Google

Knowles has set himself to work to develop a system by means of which the arc-lighting apparatus can be run during the day to charge storage batteries, the lighting capacity of the station being by this means considerably augmented. Over in Brooklyn, Mr. Knowles has already worked out this system practically, and it is understood that an extensive development commercially is contemplated there, as well as in other cities. At the present time, from his charging station Mr. Knowles runs 10 circuits, each machine feeding seven sets of batteries of 30 cells each, or 210 cells for each machine. From the generating station the current is carried to the battery station over arc-light wires placed on poles, the distance being about half a mile in this case, although one of the battery stations projected is more than a mile from the charging station. These battery stations, by the way, may be and are located in any convenient cellar or basement or other place where the rent is so low that it hardly enters into the cost as a factor at all. Another point in this system of combined lighting is, as will be noticed, that the storage batteries and arc lamps are operated over the same circuits. This is accomplished automatically by means of the polarised switch attached to each arc lamp, and to each set of batteries on the same circuit, so that the current passing through in one direction or the other cuts out or cuts in the lamps or the batteries as may be desired. When the switches on the lamps cut the lamps out, those on the batteries cut the batteries in. In practice, it is said, this system works satisfactorily, and even should one of the switches on a lamp fail, the mere fact that the arc lamp was burning in the daytime would attract attention, and cause the lamp to be switched out, as it should be. In connection with this system also, Mr. Knowles has brought out a new form of storage battery, which avoids all pasting or direct application of the active material. The plate consists, practically, of two plates, between which is placed the active material in the form of a third plate, which has been compressed separately in a special mould, and fits tightly between the two walls of metal prepared for it. The electrolyte, as usual, has full access to the active material, but the method is regarded as a pretty good cure for buckling, dropping out, &c. The metal plates are cast, it is stated, of an inoxidisable alloy which contains no mercury.

Among the classes of meters which have not received much attention may be mentioned those of the photographic class. A new instrument of this latter form has just been devised by Mr. G. W. Walker, of this city, a gentleman connected, I believe, with one of the storage battery companies. In this instrument, the current strength at any instant is marked by means of a line traced on a sheet of photographic paper, which travels before a beam of light, whose position is dependent on the current strength of the circuit, so that the needle of the meter may be said to write its record as accurately as a ray of sunshine would. The movement of the needle will, of course, vary in accordance with the number of lamps in use, and as it vibrates and travels back and forth in front of the slot, its movements are photographed immediately upon the travelling band of sensitised paper, which, of course, may be developed at any time, and will show at once what amount of current has been used at any or every moment, the quantity being determined by reference to a graduated scale before which the needle vibrates.

Although the facts may not yet be developed on your side, it would appear, from what is going on here, that the alliance between the Commercial and French Cable Companies has been made closer, news reaching this city from Halifax that the management and operation of the French cable from Sidney to St. Pierre, and thence to France, has been taken over by the Commercial Company, whose energetic manager, Mr. G. G. Ward, has been in Nova Scotia superintending the amalgamation. It is also reported that the two companies have entered into an arrangement with the Canadian Pacific Telegraph Company, whose land lines are being run in order to complete the connection with the cables at Canso. This statement is rounded off by another to the effect that, in order to secure independent connection with the United States, a new cable will be immediately laid between Canso and Boston.

[A contradiction of these rumours will be found in another column.—Ed. *E.*].

There has been a rumour current in Boston this week to the effect that the Western Union Company has applied, or would apply, for an injunction restraining the Bell Company from pushing its long-distance work The newspapers have it that the Western Union Company claims that long-distance telephony will "ruin its business;" but this cannot be the ground of complaint, even if the main assertion were true. It happens that pretty well everybody knows that there is an agreement between the Western Union and the American Bell Telephone Companies to the effect that the latter shall not go into the field of the transmission of general business messages, market quotations, &c., but it would seem that part of the work of the long-distance telephone company must violate and contravene this provision of the articles signed in November, 1879. It would also seem to an outsider that some of the work done by the exchanges over their extra territorial lines, as well as that done over the new long distance lines, must be contrary to the letter of the agreement in question; but it is being done all the same. It is, of course, possible that the American Bell Telephone Company, who are generally astute and well-advised in such matters, are well within their privileges and reservations. It is a little bit difficult to believe that the two great companies, having thus lived in peace for ten years, should now come to loggerheads, and in these days of combination one is more likely to see them come closer together than to find them falling out and getting wider apart. The 20 per cent. commission which the Telephone Company pays to the Western Union amounts, it is true, to about £100,000 a year, but in view of the large earnings from the telephone this is, perhaps, after all, not a high price to have paid for the withdrawal of the Western Union competition in the days when the Bell telephone interests were poor and struggling.

CORRESPONDENCE.

ELECTRICAL DISTRIBUTION BY MEANS OF CONDENSERS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have read with interest your article No. II. in your this week's issue, on the "Distribution of Continuous Current by Means of Condensers," by Dr. Stephen Doubrava; also article No. I., which I had not previously seen. I have been working at this subject off and on since 1886, and have taken out patents in connection with it, and feel that I might add some interesting points.

The title Dr. Doubrava has chosen for his articles is not in strict conformity with the subject matter, seeing that it is an alternating current he distributes by means of condensers and continuous currents.

I cannot follow his explanation for the non-sparking, nor do I think that his curves 3 and 4, correctly illustrate the current charges in the primary and secondary circuits of which he calls his disjunctor. Fig. 3, I think, should be something as follows (Fig. 1). The charge of the condenser commences at *b*, is

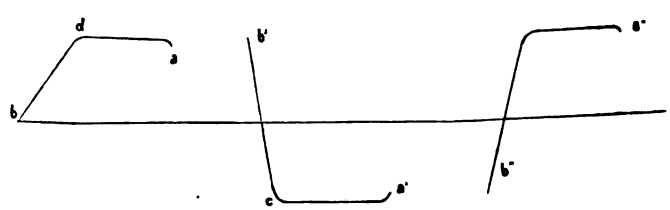

Fig. 1.

fully charged at *d*; is left charged at *a*, with a slight discharge in consequence of the break. Discharge and reversal of current commences at *b'*, is complete at *c*, left charged with opposite current at *a'*, and so on.

From the many experiments I have made, I quite agree with Dr. Doubrava that there should be very little sparking with his apparatus, but it is due to the small quantity of current he

Digitized by Google

employs. With current strengths up to about ·25 amperes and pressures of 700 volts, or perhaps higher—this was the limit of my experiments—the sparking is inconsiderable, but larger currents make serious sparking. There seems to be a cohesion in the current, which makes it occupy the most confined space in passing from commutator to brushes, even though the latter be of very large dimensions, which is well illustrated in sparking dynamos. The heat generated by the larger current is also too great for the conduction of the metal to prevent fusion, consequently the metal vapour assists in supporting the spark. The only way to spread the current over the larger surface of the commutator is to subdivide the brush and connect each subdivision through a resistance or other contrivance to the main lead.

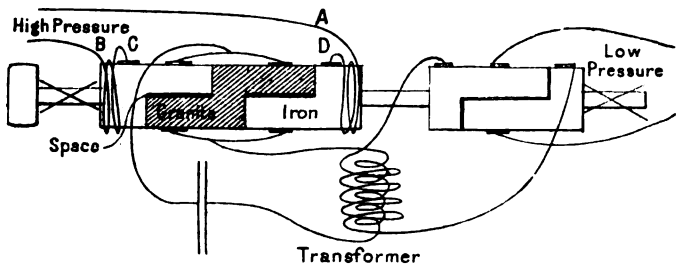

Fig. 2.

My experiments showed that a total break, as proposed by Dr. Doubrava, before the reversal reduced the efficiency, and the only way I found to obtain maximum efficiency was to make a complete reversal without a break.

The above (Fig. 2) is a diagram of the simple form of commutator I ultimately arrived at about two years ago. As will be seen, it is designed for first alternating the continuous current, and then reconverting into a continuous current after it is reduced in pressure. The high-pressure wires were connected to fixed coils of wire surrounding the two commutator blades, which were made of iron, and consequently became magnetic before reaching the commutator brushes *c* and *d*. The effect of the magnetic leads on the current in a spark was to coil it outwards from or inwards towards the axle, according to the direction of current, and to extinguish it with a loud crack, which became very loud if the current were 5 to 8 amperes.

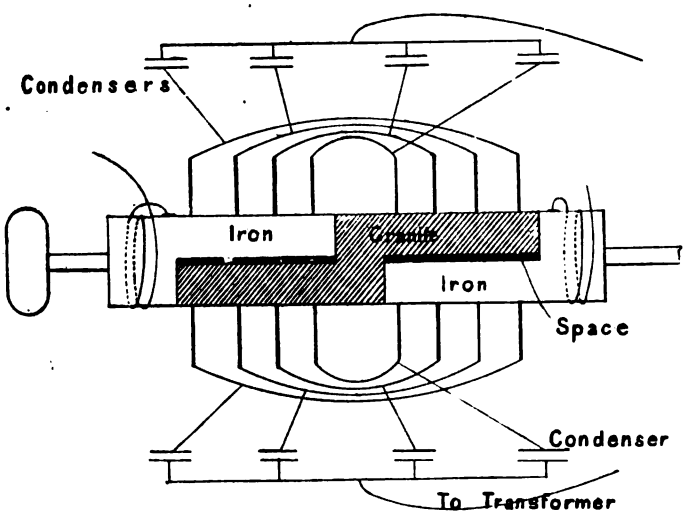

Fig. 3.

To prevent any possibility of a spark connecting the opposite sides of the high-pressure circuit through the commutator, the leaders were separated longitudinally as shown, and four brushes employed, making two pairs, one of which is connected through a condenser to the transformer and back to the other pair, the secondary of the transformer being connected to an ordinary two-way copper commutator mounted on the same axle, so that the two commutators rotated simultaneously. With this magnetised-commutator arrangement it was possible to convert 5 amperes at 700 volts into alternating currents. There is no sparking in the reconversion to a continuous current; the brushes have to be adjusted a little in advance of those on the high-pressure current. The condenser in the circuit reduces the sparking considerably. But in order to make the apparatus work continuously without sparking I made the arrangement shown in Fig. 3 of subdivision with condensers or resistances—preferably, however, condensers, because the current could never increase beyond the quantity found most advantageous and limited by the capacity of the condensers. I still found the magnetic commutators to be an advantage in making the reversal of the current sharp, which was otherwise delayed by the trifling spark momentarily short-circuiting the leads through the brushes.

I never introduced this apparatus to the public, being under the impression that it could not compete with the alternating-current system.

The applications of condensers to the alternate-current transformer system are likely to be very valuable and varied. In the first place, as a safety appliance in the distributing mains instead of a fuse, or even in the branches, a condenser applied for this purpose would prevent the troublesome ignitions and delays in rectifying that fuses often cause. The wires could never get overheated if the condenser is properly proportioned to their section. Even with a dead short circuit across the two mains just beyond the condensers no danger would arise, for the condensers will not permit any more current to pass them than the limit of their capacity, other conditions remaining constant. A less important application is as a substitute for the impedance coil in conjunction with arc lamps, &c., in this application, also it would be a regulation of the current to the lamp.

Should there be any advantage in the system of glow lamps in series, as in the Bernstein system, the condenser is the solution to the problem of perfect regulation of the current to varying numbers of lamps in series, and many circuits may be connected to the one dynamo, and in each the number of lamps may be varied without influencing the others. I have demonstrated this by experiment, twenty-four 100-volt lamps being hung up in series, which were bridged by a loop of wire one after another until the 2,400-volt circuit was short-circuited beyond the condenser, but with no variation in the current perceptible in the lamps.—Yours, &c.,

J. D. F. Andrews.

56, George-square, Glasgow, July 29, 1889.

PARLIAMENTARY INTELLIGENCE.

THE ELECTRIC LIGHTING BILLS BEFORE THE HOUSE OF LORDS.

Last night (Thursday) the House of Lords had before them several Electric Lighting Bills and Orders, when permission was granted to dispense with the Standing Orders to allow them to be read a second time and go before Committee before the close of this Session.

The first was the Metropolitan Electric Supply Bill, for which the Chairman of Committee got the assent of the House to dispense with the Standing Orders and pass the second reading. The Bill will be taken before a Select Committee of the Lords next week, when the Opposition will prolong the hearing probably for a couple of days.

Lord BALFOUR of BURLEIGH then moved the dispensing with Standing Orders, in order that the following Provisional Orders might be read a second time:—Electric Lighting Provisional Orders (No. 1) Bill, Electric Lighting Provisional Orders (No. 2) Bill, Electric Lighting Provisional Orders (No. 3) Bill, Electric Lighting Provisional Orders (No. 4) Bill, and Electric Lighting Provisional Orders (No. 5) Bill. His lordship said that these were the first of the applications under the Act of last year. A great deal of discussion on them had taken place throughout the different local authorities concerned. The first of these Bills concerned several local authorities in the country, and they were, he believed, absolutely unopposed. With regard to the Bill concerning the metropolis, moved by the Chairman of Committees, it was a private Bill. A great deal of discussion had taken place upon these Orders, and so important were the issues involved to the people of the metropolis that the Board of Trade thought it necessary to have a special local inquiry, and that inquiry extended over eighteen days before Major Marindin. A report was afterwards drawn up, and a good deal of negotiation had to be gone through, so much so that the Bill, and practically the Orders, could not be presented for second reading within the time allowed by the Orders of the House. He therefore appealed to their lordships to allow these Orders to be read a second time in order that they might have an opportunity of passing this Session.

This was agreed to, and the Orders were accordingly allowed to be read a second time.

THE STATE PURCHASE OF THE FRENCH TELEPHONE SYSTEM.

The *Journal Officiel*, of the 27th ult., publishes the text of the Act recently passed by the Chamber of Deputies authorising the Government to acquire the property of the *Société Générale des Telephones*. There are five articles, as follows :—

ARTICLE I.—The Government is authorised to accept in the name of the State the offers which may be made by the towns, public establishments, or syndicates, to deposit at the Treasury, in advance, without interest, the sums necessary for the establishment, maintenance, and working of Urban Telephonic Exchanges, and to devote the profits of each exchange thus created to the re-imbursement of the advance of which it has been the object, without other obligation on the part of the State.

An account will be rendered each year to Parliament of the arrangements in progress under this plan, and of the position of each exchange thus established.

ARTICLE II.—The Government is authorised to effect the purchase, to put into good order, and to develop the telephone exchange belonging to the Société Générale des Telephones, for which purpose an advance of ten million francs will be made by the Treasury.

ARTICLES III., IV., AND V.—[Deal with the manner in which the money is to be paid over by the Treasury, and provide that the sum required in a given year shall be included in the ordinary budget of the year, and with other purely financial matters].

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

SPECIAL NOTICE.

We are actively proceeding with the 1890 Edition of this Directory and Handbook, and New Names and Corrections to those already in the Book can now be received. Of the 1889 edition there remain unsold only a few copies, which can now be obtained post free to any address in the United Kingdom for 3s. each, or within the Postal Union for 3s. 6d.

Fresh Tables and much additional information will be found in the Handbook Section of the 1890 issue, and every effort is being made to largely extend and improve the Directorial Section.

The new Edition will be published in January next.

In order that the latest insertions and corrections may be made, new names and addresses, and corrections will be received up to about the end of December.

COMPANIES' MEETINGS & REPORTS.

The Direct United States Cable Company (Limited).

The twenty-fourth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Friday last, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. T. Finnis) read the notice calling the meeting and the minutes of the twenty-third ordinary general meeting, which were confirmed by the present meeting and signed by the Chairman as correct.

The CHAIRMAN : Gentlemen, you have had the report in your hands for some time, and I presume you will take it as read, but before asking you to approve of it I will, as usual, make some remarks upon the report. The revenue for the half-year to 30th June, including £299 for income-tax refunded, and after deducting outpayments, was £39,626, and the working and other expenses, including income-tax, but exclusive of cost of repairs, amounted to £16,676, leaving a balance of £22,950 as the net profit of the half year, making, with £11,642 brought from the previous half-year, a total of £34,592, which has been appropriated as follows :—Interim dividend of 3s. 6d. per share for the quarter to 31st December last, £10,624. 5s. ; interim dividend of 3s. 6d. per share for the quarter to 31st March last, £10,624. 5s.; proposed final dividend of 3s. 6d. per share for the quarter to 30th June last, £10,624. 5s. ; total, £31,872. 15s. ; leaving a balance of £2,719, which it is proposed to carry forward. The revenue for the half-year at the 1s. rate shows an increase of £22,118 as compared with the corresponding period of last year, but the tariff was then only 6d. per word. The half-year to 30th June is always less productive than the six months to 31st December, and it is hoped that the increase noticed in the traffic may continue, when a much better result may not unreasonably be looked for.

The expenses in London, per Abstract "A," are so very nearly the same as in the corresponding period of last year, being £8 less on the whole, that a comparison of details is unnecessary. At the stations the comparison is as follows :—Salaries and wages are £273 higher, owing partly to the additional joint station opened in September last at Boston, and partly to some

Digitized by Google

little increase which it has been necessary to make in the pay of the operators, who, for some years past, have had no advancement whatever. Maintenance and renewal of instruments cost £253 extra, principally by reason of the adoption of the "Recorder" instrument at our main-cable stations of Ballinskelligs and Halifax, and from which satisfactory results have been obtained. Travelling expenses, and repairs and renewals to buildings, &c., show a reduction of £35 and £32 respectively. Printing and stationery item is £160 higher, owing to increased consumption of message forms and stationery. This is in one sense satisfactory, showing that the Company has carried over its cable a larger portion of the Atlantic traffic. In the same way the increase of £42 in bank commission is the result of the increase in the receipts to be remitted from abroad. With the exception of the item of £800, for proportion of the expenses connected with the action of the Anglo Company *v.* French Company, which is quite of a special character, the remaining items of expenditure are practically unaltered.

On the 19th April last the main cable was broken on the Green Bank, through the fouling of the cable by a vessel's anchor. Application was immediately made for the use of the Anglo Company's ss. "Minia" to repair, but she was found to be unavailable. A speedy restoration of communication being of the greatest importance, the Telegraph Construction Company's ss. "Britannia" was at once despatched to the position of the break, and restored the cable on the 19th May, at a total cost, including cable used, of £4,474. 1s. 11d. A portion of the cable picked up during this repair was found in excellent condition, after its *sixteen years'* submersion. The reserve fund account, after being credited with interest on the investments and profit on sales of securities, and debited with cost of repairs, now amounts to £242,018. It is not on this occasion proposed to further increase the reserve fund; but it is hoped that in future this account may be regularly increased by transfer out of revenue. The investments continue, as heretofore, to be worth much more than the figure of cost at which they stand in the balance-sheet.

Now, gentlemen, I think these are pretty much the details in connection with our report, and I may mention that probably I have never on any occasion that I have addressed you had less to say than at the present time. I may, however, inform you generally about the state of our cable, as it has cost us a considerable amount during the last 12 months for repairs. I have a letter which we have only received this morning from an eminent electrician, Dr. Muirhead. He says:—"In continuation of my letter of February 28th last, I beg to say that after careful consideration of the tests recently taken of your main cable, and aided by a review of the tests taken during the early years of the cable, I have no hesitation now in giving it as my opinion that your main cable is, electrically speaking, practically as perfect at this date as it ever was. The average insulation of the cable is between 2·8 and 3 megohms at the end of the fifth minute, *i.e.*, over 7,000 megohms per knot—a high degree of insulation for a gutta-percha cable. Moreover, the steady fall in the insulation readings taken at Ballinskelligs Station on July 14th inst. prove to my mind that the dielectric is in a healthy state." I may mention to you that a fault in a submarine cable makes it impossible to work the duplex system, and as you are aware the duplex system practically doubles the working power of a cable. I am happy to say that at the present moment our cable is being worked by the duplex, and consequently it is in a perfect state. I hope it may long continue so. I have just sent for a piece of the cable picked up during the repair the other day on the "Green Bank," which will show you that a cable after being 16 years in the water, if it only finds a comfortable bed to lie upon and is not disturbed in any way, may live to a long life. As you are aware, there was a time when we said that 10 years was something like the average life of a cable, but I think we may with as much confidence say now 20 years, and I would, perhaps, go beyond that, only it is not wise to prophesy. Time passes so quickly that we will allow facts to justify the position rather than prophecy. I have thus shown you that we are perfectly satisfied with the present position of our cables. Now the next question about which I would say a few words is the question of the 1s. tariff. That tariff is earning just double the money that we earned at 6d., and that is a very satisfactory feature indeed; but still it is not earning sufficient money to satisfy the excess of submarine cables now in the Atlantic. If the number of cables there had been simply sufficient to do the work that was required of them, I believe the 1s. tariff would have been a very satisfactory one indeed. I do not see any chance of a change in that tariff, but it is possible that some of the cables may die out. At all events, if the last two cables that were laid had not been laid, I think we should have been in a very satisfactory position. If those two cables which are getting their share of the traffic had not been laid the other cables would be earning a satisfactory dividend at the 1s. rate. I have, therefore, no reason to say that the 1s. tariff does not give a satisfactory dividend, but the misfortune at the present moment is that there are more cables to do the work than are required. However, such has been the growth of telegraphy in my time that I am hopeful that it will continue to grow, and that though we have ten cables at the present moment in the Atlantic while eight could do the work, I believe there will be work for the ten cables if we are patient and trade grows in the future as it has in the past. I do not know that I have very much more to say. The law suit is still going on in France, and there is a great deal of inconsistency connected with it. Still, we must see the end of it, but as the thing is *sub judice* just now, I think it would be unfair to all parties for me to refer to it further than to say that we are persevering with the suit in the hope of arriving at a just solution. The diversion of our cable from Brown's Bank has, I am glad to say, so far proved a success. We were constantly having our cable interrupted by ships' anchors, though not intentionally, and it became a question very often with the fisherman whether he should lose his tackle or break our cable. We have tried to make things pleasant with the fishermen by telling them if they found they had picked up our cable at the loss of their anchors we would compensate them. We have done a little in that way, and it has been very justly and fairly used by the fishermen; but since we have removed our cable to the south of Brown's Bank we have not had one interruption. That is so far satisfactory. The tests of our cable I have spoken of, and Dr. Muirhead has testified that they are excellent. I think with these remarks I will now move the following resolution:—

"*That the report of the Directors, dated 12th July,* 1889, *together with the statement of accounts to 30th June,* 1889, *annexed thereto, be and the same are hereby received and adopted, and that a final dividend be now declared of 3s. 6d. per share, free of income tax, making with the interim dividends already paid a total dividend of 3½ per cent. for the year ended 30th June,* 1889."

I would just add one remark—that is, that this year only shows 10 months' working with the 1s. tariff. There were still two months of the year at the 6d. rate. Had the tariff been at 1s. the whole year the result would have been better. At our meeting six months hence, if I live and have the pleasure of addressing you, I shall be able to give you a fair statement of 16 months' working of the system at the 1s. tariff.

Mr. WM. FORD: I beg to second the motion.

In reply to Mr. HANCOCK,

The CHAIRMAN said that they had been large payers under the joint-purse arrangement to the French Company.

The motion was carried unanimously.

The CHAIRMAN then proposed, and Mr. W.M. FORD seconded, the re-election as a Director of Admiral of the Fleet the Hon. Sir Henry Keppel, G.C.B., D.C.L.

Mr. GUESDON rose to move an amendment to the effect that Admiral Keppel be not re-elected, maintaining that five Directors were sufficient.

Mr. WINDETT WOODS seconded the amendment.

Mr. JACKSON thought the time had not yet arrived for making the alteration proposed.

Mr. BOVILL presumed that the proxies had been issued and stamped at the cost of the Directors.

The CHAIRMAN, in reply, stated that the amendment proposed by Mr. Guesdon was out of order, and maintained that the question of Directors was not merely one of management, but was also one of confidence in the general body of shareholders, and was to give a certain representation to them, and in that representation the shareholders had confidence. As to the proxies, they were paid for by the directors themselves.

The motion was then put and carried with three dissentients.

The CHAIRMAN then proposed the re-election of Admiral R. C. Mayne C.B., M.P.

Mr. MEARA seconded the motion, which, after some further discussion, was declared by the CHAIRMAN to be carried unanimously.

On the motion of Mr. JACKSON, the auditors, Mr. John Griffiths and Mr. Sawyer, were re-elected.

Mr. DEARTH then proposed a vote of thanks to the Chairman and Directors, which was seconded by Mr. HANCOCK, who observed that in bad times Directors were more often deserving of the remuneration they received than in good times, inasmuch as they had greater anxieties to bear and greater work to perform.

The motion was carried unanimously.

The CHAIRMAN, in reply, thanked the meeting on behalf of his colleagues and himself, and said he thought they had done very well in their Company, considering the competition and other difficulties against which they had had to contend.

The proceedings then terminated.

Anglo-American Telegraph Company (Limited).

The ordinary general meeting of the proprietors was held at Winchester House, Old Broad-street, on Tuesday last, the Most Hon. the Marquis of Tweeddale in the chair.

Mr. T. H. WELLS (the Secretary) read the notice convening the meeting and the minutes of the preceding meeting, which were confirmed.

The CHAIRMAN said: Gentlemen, in moving the adoption of the report, which I presume you will take as read, I have, in the first instance, to apologise for the absence of our esteemed Chairman. Lord Monck has been advised by his medical attendant to take a few weeks of complete rest, and I think you will all agree with me in hoping that this will restore him to his usual health. In submitting the report I shall have a more than usually agreeable duty to perform, because although the dividend which we propose to pay is not a large one, and is certainly not sufficient to remunerate those who place their capital in such insecure property as cable property in the Atlantic, it is still by far the best dividend we have been able to pay for several years past—indeed, since 1884. Of course, you know that the increased receipts are due to the increase which took place in the tariff. The tariff has been doubled, and the number of messages has practically remained the same. This is a very satisfactory feature, and is all the more satisfactory because the six months under review are the least productive six months of the year. Already there is an indication of improved receipts since the close of the last half-year, and there is every reason to believe, or at any rate to hope, that by the time we meet you again a still more favourable result will be submitted for your consideration. Gentlemen, it must be satisfactory to you to note that while the receipts have doubled the expenses have remained practically stationary. It is true that if you examine closely the figures under abstracts "B" and "C" you will note that under one or two heads there is an increase, but these increases are exceptional. For instance, under the head of "assurance fund" there is an increase of just £500. This is due to the payment made to the late superintendent of the Duxbury station, who was unable, in consequence of ill-health, to take up his share in that fund when it was started. That

Digitized by Google

is a payment which will not, of course, occur again. In the same way, under the "maintenance of land lines" you will observe a slight increase of £600. That increase is due to the removal of our lines in Newfoundland from the roadside to the railway, a very important improvement in economy and efficiency. Our repairing ship, the "Minia," has been actively employed in making certain repairs on the other side of the Atlantic and in the removal of the Duxbury-St. Pierre cable, a cable which, where it was laid before, gave us constant trouble and caused us constant expense. The removal of the cable to its present position will, we trust, be of great benefit to us, and will lead to a considerable economy. The condition of our cables generally is a very important matter, perhaps the most important we have to deal with; and it is a subject of regret that your Directors are not able to say that they are all in a satisfactory condition. The only exception however is that of the Brest cable, which has been, as you know, a source of trouble to us for some years past. The break in that cable in the deep sea, about half way between Brest and St. Pierre is, of course, very much to be regretted. A few years ago such an announcement would have created consternation, or, at any rate, alarm, but it is received now with comparative equanimity. That is due to the skill and experience of those who have to conduct the expeditions for repairing such breakages. You know that we have in our service the captain of the ship "Minia," who is, above all, experienced in such matters. He has been directed to proceed to the spot, and endeavour to effect the repair, and inasmuch as we have something like two months of tolerably fair weather before us, there is reason to hope that before the next meeting we shall be able to report the repair of this fault. If it is not done it will not be from any want of skill or enterprise on the part of those who have the duty of undertaking the repair. I do not think there is anything else in the report to refer to, except the lawsuit which is still going on in France. About that I can add nothing to what is said in the report. The appeal may be expected to be heard in the course of the autumn. You may be aware that the amount decreed to us has not been taken into account in any way, while, on the other hand, the bulk of the expense is already written off, so that whatever comes, should anything come to us under that head, will be entirely to our benefit. Gentlemen, with these observations, I beg to move the acceptance of the report and accounts. The words of the motion are as follows:—

"That the report of the Directors and the accompanying statement of accounts to the 30th June, 1889, submitted to this meeting be and the same are hereby received and adopted."

Sir JAMES ANDERSON seconded the motion.

Mr. THOMAS SMITH had very great pleasure in supporting the adoption of the report, as he thought the shareholders would agree with the Chairman's remark that this was one of the pleasantest meetings they had had for some time past. It must be very satisfactory to observe that the traffic had increased to the extent of £68,000 in the half-year with very little increase in the working expenses. Under the circumstances, he thought they might congratulate the deferred shareholders that they were now within sight of some dividend, especially as the Chairman had stated that the increase in the traffic was still going on. So far as they could tell at present, there was every reason to hope that at the next meeting the accounts would show that the Chairman had spoken accurately in this matter. He wished to ask if the shilling rate, which would come to an end on the 1st September, was likely to be continued? And with regard to the French lawsuit, had the Directors fair hopes that commercial justice would be done to this Company if the late decision were upheld on reference to the higher Courts? The contract was a perfectly free one, and the proportion of the receipts beyond the absolute earnings of their cable by the French Company had been stated at over £250,000. Morally, no doubt, this company had a very large claim upon the French Company; but whether they would get justice remained to be seen. With the present position of the Company they had reason to be gratified, for though the dividend on the Ordinary Stock for the past twelve-months had only been 2½ per cent. and 5 per cent. on the Preference, the prospects were brighter than they had been for some time.

Mr. JACKSON agreed in a sense with what had been said as to the improved position of the Company, but there was one matter upon which the meeting would be glad of information. He did not know whether the statement published on Monday was to be taken as a financial scare, as it came out on the eve of their meeting; but most of them had seen in print a reference to a supposed danger to this Company in the shape of a Canadian cable, which it was said the Canadian Government would guarantee to the extent of £100,000. Personally, he was inclined to regard it as a "bear" announcement rather than anything else. Of course they were aware that such a cable had been talked of for a long time, and there was no doubt that the Canadian Government, like the United States and the French Governments, would like to have a cable of their own to their own shore; but in face of the fact that the year's earnings by this Company produced a dividend of 2½ per cent. only, or considerably below the rate at which the British Government, with Mr. Goschen thrown in, was able to raise money at, and remembering also that the Ordinary Shares of the Direct Company and the French Company stood at about 50 per cent. discount, it was difficult to believe that any body of men would be infatuated enough to subscribe for another competing cable. This company had now reached the end of its twenty-third year of existence, and it was lamentable to know that the starvation rate of interest of the British Funds was all that this Company was able to earn. He did not think this would be an inducement to people to throw another half-million or a million into the Atlantic, for the sake of Canadian patriotism or any other object. There was another question which he had ventilated on previous occasions, and he had the high authority of Sir John Pender in saying that the consideration of the question would be a reasonable one. They had now arrived at maturity, and they were no longer able to put the public under any obligation in the carrying out of this grand invention, which had produced a great revolution in commercial life. He thought, therefore, that the time had come when their managers and those who had the direction of these concerns, should turn their serious attention to see whether they could not possibly develop the traffic. Their most excellent Chairman, Lord Monck, stated on one occasion that it was impossible to create business; but they knew, as men of business, that that was what men were doing every day. Why, in the past two years this Company had increased its business 182 per cent. by meeting their customers in a proper way, and he again suggested whether it would not be possible to introduce the system of deferred messages—messages that would not necessarily have to be delivered within twenty-four hours. They were told that the Post Office would not acknowledge any differential rate of that sort, but that was all nonsense. He thought the matter worthy of consideration. They had at the Board men of the highest integrity, but he was afraid there was not that amount of "go" about them which was necessary to make the concern as prosperous as the shareholders had a right to expect.

The CHAIRMAN: Gentlemen, with reference to the first question, I have to say that the 1s. tariff will be continued from the 1st September. All the companies interested have agreed upon this point. I had rather not dwell upon the question raised with respect to the French suit until the decision has been received by us. Then we shall deal with it in a manner which I am sure will meet with your approval. With regard to the Canadian cable, we know just about as much as gentlemen in the hall who have read the papers. Our information, such as it is, is also based upon newspaper paragraphs. This cable is a very old scheme, I believe. It is impossible to say what people may do with their money, even Governments; but the scheme is not a probable one, and not likely to be carried out I should think. The route which is proposed involves every risk which a cable can be exposed to, including ice and icebergs. That is not likely to meet with the approval of the public certainly, and I doubt extremely whether the Canadian Government will be induced to endow it with £100,000, a year or any other sum. Then, as to the question of developing the traffic, that is one that has interested Mr. Jackson for a long time; but I do not know that I can throw any light upon it further than by saying that what he said has been listened to by our Managing Director, who, perhaps, knows more about the development of traffic than anybody in London, and I am sure whatever is valuable in it will receive his best consideration, and be given effect to as soon as possible.

Sir JOHN SWINBURNE, M.P.: With regard to the renewal fund, what is the meaning of "renewal of artificial lines?"

The CHAIRMAN: That is an expense in connection with the duplex working. It is described as an artificial line because in working duplex you have to provide an artificial line. That is the mode by which the duplex system is carried out in submarine cables, and it is a very expensive process.

Sir J. SWINBURNE: Are the electricians able to say within a mile or two where the cable is broken?

The CHAIRMAN: Yes. The distance of the fault from Brest is about 1,220 miles, and from St. Pierre about 1,460 miles. The depth of the water is from 1,800 to 2,000 fathoms. You will remember that we have already taken up one or two cables at that depth, and if we have fine weather, no doubt we shall be able to deal with this breakage successfully.

Sir J. SWINBURNE: I think it would perhaps be satisfactory to the meeting to know roughly, within £50,000, what is generally considered the cost of laying a cable between here and Canada or Newfoundland. I have heard that it is something like £600,000.

A SHAREHOLDER: How is the annual interest on the investments disposed of? There is nothing in the accounts to show whether it is reinvested or whether it is absorbed in the income.

The CHAIRMAN: It has been put from time immemorial to the renewal fund. Perhaps you were not here this time last year, when this matter was very fully discussed; in fact, a motion was made, which was defeated at that meeting, that the interest on the renewal fund should be paid into the general funds. You will find it in the renewal fund account, "interest, &c., £17,352." That is the amount of interest accrued to the account. I am afraid I cannot enter into the question of the cost of a cable to Canada, which depends on so many things. No doubt the promoters will represent the thing at much less than it would really cost.

The motion was then put to the meeting and carried unanimously.

The CHAIRMAN: Gentlemen, that constitutes the business of this our half-yearly meeting.

Mr. T. SMITH: Gentlemen, I have great pleasure in proposing a vote of thanks to our hon. Chairman and to the Board on the present occasion.

Sir J. SWINBURNE seconded the proposition, which was also adopted.

The CHAIRMAN: I thank you warmly on behalf of myself and my colleagues. I assure you that we lose no opportunity of doing justice to your interests.

The meeting then closed.

Globe Telegraph and Trust Company (Limited).

The sixteenth ordinary general meeting of this Company was held on Tuesday last, at Winchester House, 50, Old Broad-street, SIR JOHN PENDER, K.C.M.G., presiding.

The SECRETARY (Mr. Wm. Payton) read the notice convening the meeting and the minutes of the last general meeting, which were confirmed by the present meeting and signed by the Chairman as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: The report is a full one. It contains a deal of matter in small compass—and I think upon the whole it is very satisfactory. Before I begin to make any remarks upon it, I must refer to the absence of one of our Directors, a gentleman who is

Digitized by Google

largely interested in the concern, and who has always taken a lively interest in our affairs. I refer to Sir Daniel Gooch. He has been ill for some little time, but I am very glad to hear from his son, who is also on the Board, that his father is getting better, and I hope, with the fine weather, we shall see him amongst us before very long. When I addressed you last, twelve months ago, I spoke with considerable hope. I referred to the previous year, when I spoke with considerable doubt. Our surroundings were then dark, and the different telegraph companies were passing through a considerable state of excitement in this wise; that the Anglo-American Company, which is one of our largest constituents, was then fighting the question of the sixpenny tariff. Of course, a sixpenny tariff meant very much lower returns for the Globe Company. We had also at Berlin reduced our rates considerably upon other investments of ours, the Eastern Extension and Eastern Companies. I am happy to say to-day that as I predicted at our last meeting in 1888, things have become brighter, and we are able to-day to ask you to accept a dividend on our Ordinary Shares of £4. 12s. 6d. per cent., as against £3. 10s. per cent. last year. This improvement is attributable to the circumstance that the Eastern Telegraph Company, in which we are largely interested, have paid us £6. 7s. 2d. per cent. on our investment with them, while the Eastern Extension Telegraph Company have paid us £6. 6s. 9d. per cent. These two investments, which represent nearly half our total capital, pay us roundly £6. 7s. 6d. per cent. The Preference shareholders, of course, have their guaranteed cumulative dividend of £6 per cent., but it is satisfactory to find, in a return like this, that the yield to the Ordinary shareholder is equivalent to £6. 15s. per cent. on these investments. The point against this advantage is our Anglo holding, and the cost per share there is about 92 per cent. of stock. Last year the return on Anglos only showed £1. 9s. per cent., and the Direct Telegraph Company only showed £3. 10s. 3d. per cent. return; this year the Anglo shows us £2. 2s. 4d. per cent., and the Direct gives us £4. 16s. 7d. per cent. It is a favourable point that the Anglo-American Company is now earning a fair dividend. The shilling tariff has so far satisfied the requirements of the public, and the public accept it as a fair and moderate rate, and we are getting now—or rather, this Company is—just double the amount of money it received when the sixpenny rate was in force. Therefore that means an increased dividend, and we benefit thereby. So on the whole we may take it that the object with which we started, viz., the consolidation of telegraph property, so as practically to guarantee a dividend to the investor by spreading the risk as much as possible over existing telegraph systems running in various directions, has been a success. The main changes that we have made are described in our report. The Imperial German Government has taken over the cables belonging to the German Union of Berlin, and consequently of the German Union Telegraph and Trust Company. The return of capital has been received, and the Directors have very carefully considered its proper application. Our investment of 8,934 Preference Shares of £15 each in the German Union Telegraph Company of Berlin, and of 10,819 Ordinary Shares of the German Union Telegraph and Trust Company, which cost together £249,000, realised £272,500. The profit so made has been apportioned in reduction of the cost of the new investments which are specified in the report. It is satisfactory to know that an analysis of the yield of our investments at the present time indicate, on a fair estimate, that we are getting about £5. 7s. 2d. per cent. Taking off £6 of this for the Preference shareholder, there will remain for the Ordinary shareholder about £4. 14s. per cent. We have purchased some shares of the American Cable Company, and, as the report shows, on an investment of about £48,000 we get a return of £5. 16s. 11d. per cent. This stock is guaranteed by the Western Union Company. This should be a safe investment, although not a home investment. We are anxious that an international character should be given as much as possible to submarine telegraphy, because the cables must rest on many shores. Wherever the flag goes we follow, and the result of it is that we have placed ourselves in a position that wherever there are civilisation and commerce we participate more or less in their growth. The Western Union Company is a very powerful company in America, so powerful that I doubt if there is any company that possesses a greater area or mileage than it, and its guarantee is a very good one. Some people think that there is not a sufficient number of cables in the Atlantic at the present time, and I see by the papers that the laying of another cable to Canada is contemplated. If there was ever anything in the old saying of a fifth wheel to a carriage being very useless and not ornamental in any way, I think it would apply very much to the laying of another cable in the Atlantic. If we had only sufficient cables now in the Atlantic to carry the traffic—if instead of there being ten there were only eight—we should be in a very satisfactory position, but those two additional cables make all the difference. I do not think they benefit the parties who went into the business, and they rather damage those who were in the business already. I hope, however, that experience will rectify this more or less. But, whatever position these cables may occupy, we have to watch them very closely. The purchase of the Direct Spanish Debentures was a good one, because the security was in the hands of a Company who were willing to dispose of their holding as a whole, and we were able to find an opportunity of re-investing some of the German Union money. They return us about £5. 17s. 6d. per cent. We have bought some West Coast of America Shares, which appear in the accounts. This is likely to be an improving investment. The next purchase I may refer to as a change of investment is that of the West African Shares, of which we have bought 3,145 £10 shares. As this Company has been brought into the circle which encloses the continent of Africa we thought it right to take an interest in it; the prospects in the future of this Company seem to be good. It is of interest to know that our own stock at the market prices of to-day, say £15, £8½, and £23½, show a higher value over the market price of the securities which we possess by something like 10 per cent. This of itself shows the utility of this Trust, and the stability it has given to telegraph property. We have now been in existence 16 years, and while we have always been able to pay our Preference dividend, the average dividend paid on the Ordinary Shares from the beginning has been £4. 6s. 4d. per cent. We are now paying £4. 12s. 6d. per cent., and I hope it may have still an upward tendency. This shows an average dividend, taking Preference and Ordinary Shares together, of £5. 6s. 3d. Altogether, looking at the matter all round—at the investments—I doubt if they have been in a more satisfactory state than at the present time. The one shilling tariff of the Anglo-American Company has only been in existence ten months, and by the time I meet you again we shall have had a full trial of that rate. That ought to add something to our dividend. I have now given you a general detail of what is being done. Our Company is actually one of the pioneers of those Trust companies which have been formed of late years (and many of them within this year, I may say) to break up dividends and divide them. Our Company was established years ago on the principle of Preferred and Deferred Shares, and we stand in a very fair position at the present time. The 6 per cent. has always been regularly paid. The Deferred dividend is a fluctuating element. Still, all the progress that takes place in submarine telegraphy in the future will benefit the Deferred Shares, as the increased dividends we receive must be applicable to the dividend we pay on those shares. Looking at the increased value of our investments, I look forward with hope that the prosperity which is now surrounding submarine cables will continue, and that the Deferred Shares of this Company will take up the position they are entitled to take. With all the various companies I have spoken of we have great influence, because we are large shareholders in these undertakings, and what we desire above all things is to see the companies in which we are interested prosperous, because if they are the Globe Company is naturally prosperous. With these few remarks I now move—

"*That the report and accounts for the year ended July 18th, 1889, submitted to this meeting be and they are hereby received and adopted, and that a dividend be now declared payable on and after this date of 3s. per share on the Preference Shares, less income-tax, and of 4s. on the Ordinary Shares, income-tax having been already deducted, making, with previous payments, a total dividend for the year of 6 per cent. on the Preference Shares, less income-tax, and of 4⅝ per cent. on the Ordinary Shares.*"

The MARQUIS OF TWEEDDALE seconded the motion.

The resolution was carried unanimously, there being no discussion upon it.

The MARQUIS OF TWEEDDALE then proposed the re-election of Sir John Pender to his seat at the Board.

Mr. HENRY D. GOOCH seconded the motion, which was carried unanimously.

The CHAIRMAN, in replying for this renewed mark of confidence on the part of the shareholders, said that the Company was in itself a rather powerful Company, having the power to do a great deal of good or a great deal of harm. Their affairs had to be managed with great discretion, and he was very pleased by this renewal of the confidence of the shareholders that they did not disapprove of the way in which the Board had managed the Company so far as it had gone. He concluded by moving the re-election of Sir James Anderson to his seat at the Board, remarking that that gentleman was a most thorough colleague, who was always found at the post of duty.

Mr. WM. FORD seconded the motion, which was carried *nem. con.*

Sir JAMES ANDERSON having briefly returned thanks,

Mr. STEARNS proposed

"*That Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and Mr. Wm. Griffith, B.A., Barrister-at-Law, be and they are hereby re-elected auditors of the Company.*"

Mr. ANDERSON seconded the motion, which was carried unanimously.

Mr. GRIFFITH, in returning thanks, said that the auditors had verified the accounts, inspected the securities, and found everything as satisfactory as it ought to be. He then proposed a vote of thanks to the Chairman and Directors, paying a warm tribute to each and all of the members of the Board for the ability, experience, and technical knowledge which they brought to bear on the conduct of the Company's business.

Mr. JOSEPH KING seconded the motion, which was carried unanimously.

The CHAIRMAN: Gentlemen, in returning thanks on behalf of my colleagues and myself I think Mr. Griffith has very fairly pointed out that we have a rather remarkable Board—a Board who are able to take a very broad view of the varied concerns in which we are interested. I believe that that view is generally taken with a great deal of consideration and discretion. In my opening remarks perhaps I did not sufficiently emphasise the most important addition to submarine enterprise which has been made recently. I allude to the West African system of submarine telegraphy. Probably that is the completion of one of the most remarkable among the many remarkable things which have been done in connection with submarine telegraphy. We have completely surrounded Africa, and you will see that we have not been backward in seeing that that was going to be a very large and very profitable investment eventually, because if you look at the report you will find that we have already made a very considerable investment in that Company, believing as we do that it possesses a very great future. Its great future is this—that it reaches the Cape, and the Cape, I believe, is the country of the future. All the work of our philanthropists and enterprising men seems to be concentrated upon Africa at the present time, and I believe England has got probably the country most valuable for mercantile, commercial, and, above all, mining purposes, and as long as they continue to flourish it is wonderful how much telegraphy flourishes along with them. Our investment is already made there. We have sown the seed, and I believe we shall eventually reap a very good harvest. With these remarks, I beg to thank

Digitized by Google

you for the confidence you have shown in us. My colleagues and myself work as one man, and if concentration makes power, we are a very powerful Board indeed.—The proceedings then terminated.

The Edison and Swan United Electric Light Company (Limited).

The annual general meeting of the shareholders in this Company was held on Tuesday last at the City Terminus Hotel, Cannon-street, Mr. James Staats Forbes presiding.

The SECRETARY (Major S. Flood-Page) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: In accordance with my usual practice, I shall proceed to make a few remarks upon the report and accounts, to give such elucidations of the figures as you may desire, and then to propose certain resolutions. I had better go at once into the figures, and afterwards into general subjects connected with the Company. The balance-sheet I shall shortly deal with first. The debtor side shows the state of capital account, which is unaltered during the year. There have been no additions to capital during that period. The account is set forth in as simple a form as possible, and you can easily see how it is made up. Putting the different sums together of fully paid and partially paid shares the "A" capital comes to £353,478. That you know is a particular capital, which, being unencumbered with any prior charges, comes in first for the fruits of the undertaking. After that there are so many "B" shares amounting to £117,820, being the shares, in fact, which were allotted to Mr. Edison and his friends, and which stand in the position of Deferred Shares, and are not entitled to any dividend until the "A" shares have received the full amount of 7 per cent. cumulative dividend from the commencement of the Company. Sundry credit balances are £4,711, being money for which we are indebted to outsiders, and about that item I have merely to say that it is more favourable than it was last year, when it stood at £10,214. That is to say, that we have managed to bring down our indebtedness outside capital to £4,711. The last item is not the least satisfactory one—profit and loss as per appropriation account, £44,037; that is as against last year in round numbers £25,000. On the other side of the account we show what we have to represent that money. There you see that the cost of patents, goodwill, preliminary outlay, loss on working as per last balance-sheet, amount to £274,991. During the year we have spent under this head £13,999 in addition, but we have realised in diminution of that sum, by sale of plant and other sums which we have to receive, £12,560. Then we thought it a prudent thing to disembarrass the amount of £12,000, which we held in the Manchester Company, under an agreement by which they were licensed by, and had certain advantages from, our Company. These shares, amounting to £12,000, we transposed. They do not disappear, but come into the accounts further down. The further reduction of losses on realisation of sundry installations, taken over at the date of the amalgamation, comes in among capital outlays. The Directors have, of course, from time to time explained the nature of this business when it was taken over. It had a number of very good elements, but it had some very bad ones, and our business from year to year has been to eliminate the bad from the good, and to charge to the working of the undertaking as opportunity offered the losses which were made in getting rid of these bad bargains. I am glad to say that I think we have, so far as we know, come to the very end of that unfavourable side of our business, and I should just like you to realise the effect of that. The asset cost of patents, goodwill, preliminary outlay, &c., must be looked upon in the sense of not being a concrete tangible thing, such as chairs, tables, or anything of that sort, and, therefore, it is different from the items you find set out below, which are concrete things, such as the Manchester Edison-Swan Company's shares, investments, and freehold property. They are something having a current and immediate value. The other item has a value no doubt. It has the value represented by the dividend which from time to time you will be able to pay on your capital from the going concern in which you embarked. But it strikes me as being a satisfactory thing that the result of our working for the year has enabled us to reduce what I may call the dead asset, thereby very considerably adding to the living asset. If you cast your eye over the items you will find that the cost of patents as per last balance-sheet was £274,991 (that is how we began); whereas if you look further down the page you will find it is reduced to £235,614—in fact £39,377 less than they were. As a matter of fact, I suppose that they are well worth what they stand for in the balance-sheet, but if they were well worth £274,000 it is much better that that amount should be in figures £39,000 less, because while their real value does not diminish, there is the other hypothesis, that they are not worth so much, and we are so much better off. Then, coming to what I call a living asset, the Manchester Edison-Swan Company's shares—£12,000—I have to observe that that is not a particularly productive asset at the present moment, because it stands in the same category as the shares in this Company paid to Mr. Edison, £117,000. It is deferred to the capital provided by the Manchester Company for establishing their business. But some day one may hope that in this electric lighting business, which is showing great signs of expansion, that which was not a profitable asset may in the future become a very profitable one. I think our own shares are a very good illustration of that. In two or three years the position has so changed that we are able to meet under circumstances altogether different and much more gratifying to both Directors and shareholders than on any former occasion. Investments amount to £27,500. They are for good money representing well-invested capital. Freehold property stands at £27,991. That covers the possession of the land and the factory where we are now manufacturing our lamps at Ponder's End, and in London the Green-street site, and also a remnant of property that we have at Newcastle. Taking these three together I think we may say with confidence that they represent £27,991, which is a great deal less than their actual value. Plant and stock amount to £40,406. Of course, our factories are fitted up with plant and stock, and we have from half-year to half-year a great deal of tangible concrete value in that form. Of course the value of such things depends upon their being part of a going concern. If we had to anticipate the possibility of the business stopping, and these appliances being thrown out of gear, they might not be worth 20s. in the £1; but as parts of a going concern, producing profit, they are certainly not over-estimated at that price. Office furniture is so small that it almost wholly disappears. It is being written down from time to time, and I daresay the time is not distant when we shall have redeemed all our furniture. Debtors are £29,221, but we believe they are all good debts. Cash at bankers and in hand is £29,206. Well, now, in like manner, compared with the corresponding values of the money last year, that item has increased. It stood at £125,800 last year, whereas it is now £166,610, or in round numbers £41,000 to the good, and I think we may congratulate ourselves upon the fact that we have a credit balance-sheet highly satisfactory, and indeed representing the full value of the debits on the opposite page—that is to say, the full value of the capital invested. We now come to profit and loss account—that, in fact, is the trade account. There, again, I am happy to congratulate you upon the realisation of what has been predicted from time to time, that this business of ours only wanted time to develop and to develop rapidly. It has grown with some rapidity during the last year. You remember that in the preceding twelve months we showed the not inconsiderable advantage of having realised about £25,000. For reasons which were explained at the time, and which the judgment of the proprietors then, as I daresay it will now, commended, that amount was not distributed, but was kept in reserve. As compared with that figure, the profit this year is much larger. I had better take you through the items, however. You will see from the debit side of the account that we brought forward stock on hand (and that stock means lamps and materials connected with the manufacture of lamps as distinguished from the value of plant in the factory itself) to the amount of £19,590. During the year, in order to create the article we sell, we have had to spend in wages, purchases, cost of installations, &c., £62,529; salaries, Directors' fees, office expenses, insurance and general charges are £8,562; and then there is a small item of a special character, £523, which will disappear from the accounts in future, Mr. Swan's particular bargain with the Company having terminated. Depreciation on plant is £1,394. Reserve for Manchester Edison-Swan Company is a small amount in the nature of damages we received. Income tax is £257. Then, on the other side of the account, by sale of lamps, fittings and charges for work done, we received £111,715, for interest on the several investments £1,047, Messrs. Davidson and others £2,140, which was rather in the nature of an accidental item, being damages as the result of litigation with them for having infringed our lamp, they having had to pay the penalty. Stock on June 30th stood at £25,985. We began the year with a stock valued at £19,500, and we end with one valued at £25,935, or in round numbers £6,000 more. That stock must in the nature of the case increase from year to year because it bears a proportionate relation to the volume of our business. When you have a large business you must have a large number of lamps on hand to meet the extended area. When you have a smaller business the stock must be somewhat less. You will see that the value of the business this year is £112,763. Last year it was £88,404. Therefore, our sales increased by £24,000, and the increase in the stock is in about the same proportion. Now we come to the expenses, and there is rather a gratifying feature about them. We have often said here that the business was of a character which involves, compared with some other businesses, a very large sum for fixed charges. Whether you produce 100,000, 200,000, or 300,000 lamps there are of necessity certain fixed charges, such as rates and interest, and the outlays on the factories and our official salaries, and things of that sort, all charges of a general kind, as distinguished from charges for wages or material, which are incidental to the manufacture itself. Now, looking at that it is so far satisfactory, that whereas the cost of our business in 1888 was £70,000, in 1889 it is £73,365, so that you have an increased sale amounting to £24,000 at an increased cost of £3,500, and the result of these two things operating together is to increase the balance from £25,000 odd last year to £47,729 this year. That is the result of the year's working. We shall now come presently to the appropriation of the balance, having brought you down to the fact that the balance-sheet is more satisfactory, in the sense of the living asset being beyond the dead asset figure, and the profit and loss account, showing the result of a large increase of profit legitimately made, and we shall take you to the various paragraphs of the report. Only I have, in telling you that, pretty nearly exhausted the whole of No. 2 paragraph. It shows that there is a credit balance of £47,729 on the working of the year. It deals also with the £25,123 profit on working brought forward from last year, which we did not divide for reasons that I have explained; and then it describes how the Directors deal with the total of £72,852. We were from the first face to face with the practical question of the distribution of dividend, and the distribution of dividend in these joint stock companies is one not without its thorny places, so far as the responsibility of the Directors go. They are, like other trustees, obliged to consider what the ultimate consequence of their action will be in dealing with a trust, and there has been so much litigation—so much partially-made law—as to what is capital and what is profit that we have been obliged to be very particular indeed in the consideration of these matters from year to year. Of course it is more or less an abstract question. There is really no settled law upon these subjects by which directors can stand hard and fast. They are in the unfortunate position of having to determine in the absence of specific law what they ought to do in justice to the shareholders, and with due regard to their own protection as trustees. We have thought it judicious to write down everything in the nature of a loss which has accrued since this business was initiated. We went into it with our eyes open. We knew that there were some bad bargains, and the sooner

Digitized by Google

we got out of them the better. We did get out of them, from time to time having written down considerable sums for those losses. In 1884-5-6 we had, indeed, a certain amount of those losses, and in the balance sheets they were dealt with by letting them remain in capital account as part of the goodwill. The words are very explicit, "By cost of patents, goodwill, preliminary outlay, loss on working," &c. Well now, we have eliminated every one of these things, and by appropriating £28,815. 14s. 2d.—which is, as far as we can ascertain at present, the last item which is likely to trouble you under the head of losses—in conformity with the absolute discretion invested in the Board under clause 89 of the Articles of Association, we think we have done what is exceedingly prudent, as men of business, and something which I am sure, if you were as intimate as we are with the circumstances, your judgment would commend. We have done it this time, because we feel we can afford to do it. After that deduction, which is one of the items diminishing your dead asset to that extent, we have still a very large sum of money for distribution; and we have, under Clause 89 of the Articles of Association, created a reserve of £4,595, and the Directors recommend the appropriation for dividend, in accordance with clause 87 of the Articles of Association, of 7 per cent. upon the amount paid up on the "A" Shares in respect of the year ending 30th June, 1889; so that the outcome of the working for the year is this, that for the first time in the history of the Company the profits of the business have justified the full dividend for the year on the "A" Shares. But that dividend is not a dividend resting on the profit of a particular year. It is a cumulative dividend. Therefore, where in any year the profits are not sufficient to pay 7 per cent. the balance becomes a charge on the extra profits of future years, and if you are familiar with the accounts in the balance-sheet we have continually brought to the knowledge of the proprietors that the Deferred "B" Shares are entitled to a quarter of the profits after 7 per cent. is paid on the "A" Shares. The preferential accumulative dividend amounts to £121,374. 3s. 10d., so that the appropriation of profit for this year and in future years will be 7 per cent., which is all you can divide upon the "A" Shares; but such a further sum as the money will run to in order to put into your pockets accumulations in respect to previous years. Having exhausted the purse so far as the 7 per cent. required it, there was still enough left to wipe out some of the arrears of the accumulations, and upon that we propose to take a further 3 per cent. on account of the arrears of preferential dividend in respect of the "A" Shares, so that the dividend is in fact 10 per cent. What one would like to impress upon the proprietors is that it is 10 per cent., not in virtue of any right of the proprietors to receive 10 per cent. in a particular year—they are only entitled to receive 7 per cent.—but in virtue of the 3 per cent. coming back into their pockets in respect of the money which might have done, but did not find its way into those pockets a little earlier. It is in fact paying up old scores. I must qualify what I have said by this. When these arrears are wiped out, as it is supposed they will be, and towards which we have given a modest contribution this year, if the business progresses in anything like the ratio it progressed last year, that 3 per cent. will be made somewhat larger. The 7 per cent. cannot increase; the 3 per cent. will, assuming the work of the Company to go on progressing for the next few years. Then the "A" Shares stand in this position. Up to 7 per cent. they take the first fruits, and over 7 per cent. they participate *pro rata* with the £117,000 "B" Shares. I have now exhausted that. When I come to the appropriation account I shall have to show you that the appropriation of 7 per cent. and the 3 per cent. on account of arrears does not quite exhaust the purse. Paragraph 3 is more general, and turns upon the position and future of the Company. I suppose this is an occasion when, without being hilarious, we, the Directors and shareholders, may really congratulate ourselves upon the improved position of the Company. Everybody knows that in the few years that have elapsed since the initiation of this Company we have gone through a great many troubles. We have had litigation, we have had to defend patents, we had many people ready to deprive us of the advantages of our venture, if they could do it, and I dare say the shareholders have very little idea of the amount of serious anxiety and responsibility which the position of those questions threw upon the shoulders of the Directors, because although you have the most eminent counsel advocating for you, though you have the most eminent scientific witnesses giving evidence for you, there are always two sides to a question, and great interest being at stake involve great efforts on both sides. The antagonistic side fight hard for a possible victory. The nature of these things is very much this: Learned counsel use the best arguments, eminent scientific witnesses give the best evidence they can for you, and then the other people tell their story. Sir Horace Davey makes a very good reply to Sir Richard Webster, and some other scientific gentleman makes a very good reply to Sir Frederick Bramwell, and after those replies are heard and that evidence is given—the prosecuting side—the plaintiff, as it were—does not feel so very sanguine. The learned counsel begin to vacillate a little in their feelings about matters, and they come to the Directors, who are watching the proceedings, and they say, "Well, we think it is all right, but it might not be." Now, then, what are you going to do? I assure you, having gone through with our excellent Deputy Chairman, Mr. Leyland, Viscount Anson, and the other Directors, we had a *mauvais quartier d'heure* it was not easy to decide. When we are so confident in our right we feel inclined to go on and win, and not listen to a compromise, for people are apt to say no compromise can be so advantageous as to succeed when you are in the right. That is the sort of thing we have had to do two or three times over. Happily it is all gone. There has been a great deal of litigation, but, at all events, reasonably speaking, we believe that the patents of this Company are beyond attack. It was really in respect of the Woodhouse and Rawson Company that we felt for the first time—and certainly with greater intensity than I ever remember having experienced—the feelings I have described of the sense of responsibility of deciding what to do; but since then the same old friend with a new face started up in the shape of the Brush action. Then there were fluctuating doubts that we had to decide, and the result of our decision was that we have got all we went for. If we had not got all we went for, and they had got all they went for, your position would have been entirely different from what it is. We doubt whether there would have been any dividend to pay. Certainly if the decisions that we arrived at had not been arrived at it would not have been, as business men, prudent on our part to pay any dividend. Now we pay it without the slightest compunction or fear that to do so is in the least degree unsafe. I have anticipated paragraph 4. That shows that all this business over the Woodhouse and Rawson suit cropped up again, and Mr. Justice Kay gave a decision against us, but in favour of the Cheesborough patents. He declared the Edison patent to be invalid. That was a dreadful thing to contemplate, and we determined to appeal, and we were happy enough first of all, by dint of the goodness of our case, and not less by the splendid energy and ability of the learned gentlemen who conducted it, and especially of the Attorney-General, we were successful in a strong Court of Appeal in the most conspicuous way in getting the decision of Mr. Justice Kay reversed. Well, of course, nobody likes to be beaten, and the Brush Company, although they have got an American taint about them, did not like to be beaten, and so they having reserved the right to appeal to the House of Lords, we were face to face again with these things that I have described. This is a capital judgment, but there is the House of Lords, and I know something about the House of Lords, but there was at one time the possibility of having our position greatly damaged by that appeal. Then wise counsel prevailed, and we, having established our rights, were not particularly anxious to use them either harshly or ungenerously to the Brush Company; therefore we did not go in for exacting the uttermost farthing. We made something in the nature of a compromise of a highly satisfactory kind to us, and, as I understand, the Brush Company are greatly pleased with it; so all I can say is, that we are pleased all round. They have ceased to make lamps. They have handed over to us the benefits from certain patents of theirs—I daresay they are worth something—and they pay the taxed costs of litigation, and I think that is a very good solution for us, and I think it is a very good solution for them, so we shall have no more litigation of that kind. That I believe is the end of the chapter, as far as the report goes. Now, what I should like to do is to impress upon our absent friends the fact—because I cannot disassociate from the company any parts of it—but for the forbearance and confidence of the shareholders it would have been impossible for the Board to feel that confidence in their litigation which has carried them through it. Therefore we are all being rewarded. You are being rewarded for your forbearance to and confidence in us, and we are being rewarded because our judgment, hard work, and anxiety have resulted in your undertaking being put on perfectly safe ground, and on the fair way to be made a very profitable enterprise. I take this opportunity of thanking our able legal advisers and our official staff, not least our friend the Major, for the great assistance they have given. There is one item which is quite new, and as to which my colleagues and myself are most anxious that there should be no mistake on the part of the proprietors. I am sure we should be, notwithstanding any idea that we have formed of our services, exceedingly uncomfortable if the proprietors were induced to accept this report without a thorough understanding of what the position of the Directors in regard to their remuneration means. The Directors' remuneration is fixed in accordance with clause 66 of the Articles of Association. This Company is formed on a basis very common—I was going to say almost uniform—among joint stock enterprises so that the Directors are partners in the profits. They receive remuneration more or less for their services, and they take it for better or worse until the profits themselves exceed a certain figure. When they do the Directors participate proportionately in the increase. As this is the first time this question has been raised I think it is only right that you should understand it, because humanity is a curious compound, and I myself have seen a great deal of these things, and I find that the best plan is to be perfectly outspoken and to have a perfect understanding with your friends and employers. The conditions upon which the Board serve the Company are set forth in the Articles of Association. Having read the clause alluded to, he continued: That is the contract as between the Board and the shareholders. I do not know what the feelings of the shareholders may be, but looking at the fact that we have had some very hard work (and I think I am entitled to speak with some authority on such matters) in proportion to the visible funds of the Company—for we have worked out of all proportion to that, and have had greater anxiety responsibility, and labour than in some great financial and great railway companies—we think we are fairly entitled to that money. It is ours, of course, by right, but I think we should not be inclined to press, right against the sense of our own judgment, that it was right or against the sense expressed by the proprietors if in their view they thought it was not right. During the early days of the Company we felt that we ought to forego some remuneration, but after the vast amount of labour that we have had we think we are entitled to it, because the Company is now in a position to pay it. We have, therefore, no hesitation in claiming it, that claim being thoroughly understood by the proprietors, and I hope not only understood but greeted with readiness. He concluded by formally moving the adoption of the report and accounts.

The DEPUTY-CHAIRMAN (Mr. F. R. Leyland), in seconding the resolution, said he would like to add a few words to what the Chairman had said—and said so well—by way of congratulating the shareholders on the position of affairs laid before them. He thought that if any gentlemen were to refer to the first accounts that were laid before the shareholders, and compare it with the statement of affairs now, he thought it would be readily admitted that there was good ground for congratulation. They started in 1884 with the management expenses at £26,350, and they had succeeded in bringing them down to £8,562. They started with a loss of £28,814 in the year, which they had converted into a profit of £47,719 in the year. These were facts for which the Directors

Digitized by Google

might fairly claim credit, and he had no doubt it would be given to them by the shareholders. They had had great difficulties to strive against. In addition to bringing down the expenses they had had their titles to fight, which had been a troublesome matter. As to their arrangement with the Brush Company, they had not given up anything great or material. The only thing that they had given up was their right to sue them for the damages we had incurred by the infringement. He thought they were acting wisely in foregoing that claim. On the other hand, the Brush Company had given way entirely. They had paid their taxed costs, agreed at a sum of £11,500. Then they had raised an action against us for some alleged infringement of patent that they held. They did not think there was much in that, but they thought it a very desirable thing to have no more litigation, and they agreed to take licenses of all the patents of any description held by the Brush Company, paying a royalty of ¼d. on the lamps made, a further stipulation being that the royalty in one year should not exceed £375.

Sir JOHN LUBBOCK, Bart., M.P., rose for the purpose of congratulating the Board on the very satisfactory report and balance-sheet which they had been able to present. He thought he was the only one present who had acted as a Director on the other companies taken over by the present Company, and consequently in that capacity he was in a position to form a right impression as to the difficulties which the Board had had to contend against and he wished to thank the Chairman, Deputy-Chairman and Directors and the Manager for the very able manner in which those difficulties had been overcome. As a shareholder in the Company, he might say that he not only agreed that the Directors should receive all that they were entitled to, but he believed it would be to the interest of all in the future that the Directors should have an interest of the kind in common with the shareholders, seeing that it was of a very moderate character for the great amount of work that they had had to perform.

The CHAIRMAN, in answer to Mr. Philip, said that the Swan Company were shareholders in this Company to a very considerable extent. Of course they would get in their capacity of a company their dividend in bulk. The shares in the Swan Company were held in bulk at the present moment, and the dividend would go into the balance-sheet of the Swan Company, and so would find its way through that channel into the pockets of the proprietors in due proportion.

The resolution was then carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. LEYLAND, the dividends recommended of 7 per cent. on the amount paid up on the "A" Shares in respect of the year ending 30th June, 1889, and of 3 per cent. further on account of the arrears of preferential dividend on the "A" Shares in respect of the year ending June 30th, 1889, were formally declared.

The CHAIRMAN then moved, and Mr. LEYLAND seconded, the re-election of Viscount Anson and Mr. Ernest Villiers to their seats at the Board.

The motion was carried unanimously.

Mr. SANDEMAN next proposed, and a SHAREHOLDER seconded, the re-appointment of the auditors, Messrs. Welton, Jones and Co., which was also agreed to *nem. con.*

The CHAIRMAN spoke in warm terms of the assistance Mr. Welton had rendered the Company.

The CHAIRMAN here took occasion to refer to the forthcoming visit of Mr. Edison to Europe, and expressed a hope that the great inventor might see his way to visit London, when the Company might have the honour, which the whole of the civilised world owed to him, of affording him some recognition of their appreciation of his merits and great inventions, more especially as they were associated with him in carrying out those inventions.

On the motion of Mr. WILSON, seconded by a SHAREHOLDER, a hearty vote of thanks was passed to the Chairman and Directors, which brought the proceedings to a close.

The Cuba Submarine Telegraph Company (Limited).

Report of the Directors for the half-year ended 30th June, 1889, to be presented at the thirty-sixth ordinary general meeting of shareholders to be held on the 7th day of August, 1889:—

1. The Directors beg to submit, duly audited, the balance-sheet and accounts for the half-year ended 30th June last.

2. From these it will be seen that the gross receipts (including the balance brought from last account) amount to £24,980. 1s. 11d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable, and the expenses in connection with cable repairs) to £8,434. 17s. 2d., leaving a sum of £16,545. 4s. 9d. to the credit of revenue account.

3. Of this the sum of £6,000 has been added to the reserve fund, increasing that fund to £90,000.

4. The dividend on the Preference Shares will absorb £3,000, and leave £7,545. 4s. 9d., out of which the Directors recommend the payment of a dividend on the Ordinary Shares at the rate of 9 per cent. per annum, free of income-tax, the balance, £345. 4s. 9d., being carried forward to the current half-year's account.

5. The Batabano-Cienfuegos Cable, mentioned in the last report as then showing sign of breaking down, was repaired by the Company's engineer, Mr. Keith, in May, several faults having been cut out, and wasted parts replaced by new cable to the extent of seven knots. Unfortunately, however, this cable ceased to work on the 13th inst., and Mr. Keith has again proceeded to its repair; meanwhile the Company has arranged for the use of the Government land lines as before. This section, which is a portion of the original 1870 cable, is in some places in a worn-out condition, and its continuing to work without frequent repair can hardly be expected. The Directors have therefore decided to have it duplicated, and this will accordingly be done without loss of time.

6. The other cables continue in good working order.

7. In consequence of representations made by connecting companies, the question of a reduction of this Company's rate for transit messages has for some time occupied the attention of the Board, and as the recent establishment of cables by a French company, connecting Hayti, Curacao, and Venezuela with the Island of Cuba, will, it is hoped, result in a permanent addition to this Company's traffic, the Directors have thought the present a favourable opportunity for lowering its rate with the least prejudice to the receipts of the Company. The reduction, which came into force on the 1st inst, will entail some loss of revenue, but this, it is anticipated, will in course of time be counteracted by the expansion of the Company's business. One or two unimportant modifications of the local rates have also been made.

8. The Director who retires from the Board at this time is Mr. Neil Bannatyne, who, being eligible, offers himself for re-election. Messrs. Gane and Jackson, the auditors, who were elected at the extraordinary general meeting in May, also retire, and offer themselves for re-election.

United River Plate Telephone Company (Limited).

Report of the Directors to be presented to the shareholders at the third ordinary general meeting to be held at Winchester House, 50, Old Broad-street, E.C., on Thursday, the 8th August, at 12 o'clock.

The result of the Company's operations during the year ended 31st March last, after paying all working expenses abroad, debenture interest, London and other charges, is a profit of £32,850. 13s. 10d., from which has to be deducted the sum of £14,689. 6s. 8d. for loss on exchange, leaving a net profit of £18,161. 7s. 2d., increased by the balance of £1,666. 2s. 6d. brought forward from the previous year, to £19,827. 9s. 8d. Out of this

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.

THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

an interim dividend of 3 per cent., or £8,250, was paid in January last; and the Directors recommend that out of the remaining balance of £11,577. 9s. 8d., a further dividend of 3 per cent., or 3s. per share, free of income tax, be now paid, which absorbs £8,367. 2s. 6d.; that £2,000 be placed to the depreciation and renewal fund, thereby increasing it to £7,000; and that the balance of £1,210. 7s. 2d. be carried forward to the credit of profit and loss account for the current year.

The Directors record with satisfaction that the 5,000 new Shares referred to in their last report, and offered to the shareholders *pro rata* in August last, were readily subscribed for, and the shareholders will observe that the capital expenditure during the year amounted to £35,070. 2s. 11d., which, however, includes the purchase of the additional business at Rosario, mentioned in the directors' last report, and to meet the cost of which, 3,000 shares were issued to the vendors, the share capital issued being thereby increased to £290,000, as shown in the balance-sheet. With this purchase, and the amalgamation consequent on it, the Company's business at Rosario is fully consolidated; and the further capital expenditure during the year has placed the Company's whole system in the Argentine Republic on a sound and efficient footing.

The Directors have pleasure in pointing out that, as shown by the figures in the balance-sheet and profit and loss account, the business of the Company has steadily and considerably developed and increased in the past year, the gross receipts in the River Plate for the year having been £81,866. 2s. 4d., as against about £66,092 for the preceding twelve months. The net results, however, has been effected by the loss in exchange, an item absolutely beyond the Company's control, which amounted to £14,689. 6s. 8d., as against £10,775. 19s. shown in the previous balance sheet. The Directors are now considering the advisability of adopting measures in some degree to meet this loss in exchange, while they are glad to say that the reports received from Buenos Ayres since the 1st April continue to show a steady increase in the Company's receipts.

In accordance with the understanding at the last general meeting, Mr. George Cooper and Mr. Alfred Le Rossignol joined the Board, and have since given the Company the benefit of their experience in the River Plate.

Under the Articles of Association Mr. Frank W. Jones and Mr. Thomas Lloyd retire by rotation at this meeting. Mr. Jones, being eligible, offers himself for re-election, but Mr. Lloyd does not seek re-election. Major Henry Fitzgerald has also resigned, and while the Board has received Mr. Lloyd's and Major Fitzgerald's resignations with great regret, recognising their services to the Company, they do not propose any other gentlemen to take their place, as the Board will thus be reduced to the original number of seven, which reduction, as explained at the last general meeting, has been for some time contemplated.

The Auditors, Messrs. Cooper Bros. and Co., also retire but offer themselves for re-election.

If the dividend herein recommended be approved at the meeting on 8th proximo the warrants will be posted to the shareholders that evening.

The Anglo-American Brush Electric Light Corporation (Limited).

An extraordinary general meeting of the shareholders of this Corporation will be held at the office of the Corporation, 112, Belvedere-road, Lambeth, London, on Wednesday, the 7th of August, 1889, at 3:0 p.m., when the subjoined special resolutions, which were unanimously passed at the extraordinary general meeting of the Corporation, held on the 22nd of July, 1889, at the Cannon-street Hotel, London, E.C., will be submitted for confirmation as s ecial resolutions:—

Resolution No. 1.—"*That it is desirable to reconstruct the Anglo-American Brush Electric Light Corporation (Limited), and that with a view thereto the Corporation be wound up voluntarily, and that J. B. Braithwaite, jun., and E. Garcke, be, and they are hereby, appointed liquidators for the purposes of such winding up.*

Resolution No. 2.—"*That the said Liquidators be, and they are hereby, authorised to consent if required to the registration of a new Company, to be named 'The Brush Electrical Engineering Company, Limited,' with a Memorandum and Articles of Association which have already been prepared with the approval of the Directors of the Corporation, but which are to be subject to such alterations and modifications (if any) as may be found expedient.*"

Resolution No 3.—"*That the draft agreement submitted to this meeting and initialled by the Chairman for the transfer of the business and property of this Corporation to the new Company shall be, and the same is hereby, approved, and that pursuant to Section 161 of the Companies' Act, 1862, the Liquidators shall be, and they are hereby, authorised to enter into an Agreement with such new Company (when incorporated) in the terms of the said draft, and generally to carry the same into effect with such (if any) modifications as the Liquidators may find expedient.*"

NEW COMPANIES REGISTERED.

THE GENERAL ELECTRIC COMPANY (LIMITED).—Registered by Tamplin, Tayler and Joseph, 165, Fenchurch-street, E.C., with a capital of £60,000, divided into 7,000 First Preference Shares, 1,000 Second Preference Shares, and 4,000 Ordinary Shares of £5 each. Object: To acquire and take over, as going concerns, the business carried on under the style of the General Electric Company, at 71, Queen Victoria-street, E.C., 22, 23, and 24, Garlick-hill, E.C., and 71 and 73, Bentham-road, South Hackney, in the county of Middlesex, under the style of the General Electric Company; also the business carried on in Clegg's-court, Chapel-street, Salford, in the county of Lancaster, under the style of the Manchester Electric Works Company, and the several patents, goodwill and other assets of the proprietors of such businesses, and with a view thereto to enter in two agreements mentioned in Clause 3 of the Company's Articles of Association, and to carry the same into effect with or without alteration. The first subscribers are:—G. Binswanger, 71, Queen Victoria-street; J. H. Ward, 23, Lower Phillimore-place, Kensington; H. Hirst, 71, Queen Victoria-street, E.C.; S. Smith, accountant, 159, Milkwood-road, Herne Hill, S.E.; G. S. Joseph, 165, Fenchurch-street, E.C.; A. R. Bernhard, Hillbrow Villas, East Finchley, N.; H. Heritage, 7, Wendover-road, Harlesden, N.W. The number of directors shall not be less than four nor more than nine, and the first shall be Gustav Binswanger, Max Binswanger, and Hugo Hirst, and two directors to be appointed by John Henry Ward. The two directors so appointed shall be paid out of the funds of the company £210 in any year in which the profits of the company shall be more than sufficient to pay a dividend of 10 per cent. on the capital paid up.

The company will continue to be a private concern and the management remains unaltered.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended July 26, 1889, amounted to £3,163, as compared with £4,592 last year.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of July, 1889, amounted to £54,248, and to £48,735 in the corresponding period of 1888, or an increase of £5,513.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of July, 1889, amounted to £42,876, and to £35,233 in the corresponding period of 1888, or an increase of £7,643.

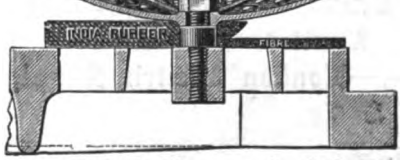
UNITED RIVER PLATE TELEPHONE COMPANY.—The report of the directors of this company for the year ending the 31st of March announces a further dividend of 3 per cent., or 3s. per share, tax free, recommending that £2,000 be placed to the depreciation and renewal fund, thereby increasing it to £7,000, and that £1,210 be carried forward.

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY.—A half-yearly interim dividend at the rate of 6 per cent. per annum on the Preference Shares has been declared by the directors of this company, payable August 1.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 26, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £1,697, as compared with £3,864 last year.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 586.—Vol. XXIII. FRIDAY, AUGUST 9, 1889. Price Fourpence.

NOTES.

The proceedings before the Select Committee of the House of Lords, which is now engaged in considering the metropolitan electric lighting schemes, have not so far been of a very interesting character. One of the chief witnesses was Major Marindin, who was examined at great length on several points connected with the recent Board of Trade Inquiry. On Wednesday, after being slightly amended, the Order of the London Electric Supply Corporation was passed, in spite of the strenuous opposition of the St. James' and Pall Mall Company. Yesterday the Order of the Westminster Electric Supply Corporation was passed.

In another column will be found a letter addressed by the St. James's Vestry to the Board of Trade protesting against the handing over of the powers of the local authorities to the County Council, and very pertinently pointing out that since these powers are vested in the local authorities by the Principal Act, the action of the Board of Trade cannot do more than give concurrent powers to the County Council. A state of things which must lead to unfortunate results.

The alternate-current motor, designed by Mr. Mordey, and discussed by M. Leblanc in the Paper which we abstract from *La Lumière Electrique*, made no appearance in Mr. Mordey's recent deliverance on "Alternate-Current Working," from which (seeing also that the patent is not of very recent date) we may draw the inference that the inventor himself lays but little stress upon this particular design. Nevertheless, as representing a distinct type of motor, and one possessing certain singular advantages, M. Leblanc's investigation of the properties of the system is not without importance, and will be found by the student both interesting and instructive. In spite, however, of the advantages alluded to—including self-starting, self-excitation, great stability in speed, maximum torque and minimum impedance attained at normal speed—it is to be feared that the presence of a varying and intermittent current in the armature is a drawback which will not easily be overcome. We may add that M. Leblanc's paper follows the lines of Mr. Mordey's specification with considerable fidelity.

In the discussion of alternate-current motors, and indeed of electric motors in general, sufficient stress is seldom laid upon the distinction between the *transmission* and the *distribution* of motive power. It requires no argument to prove that these are two distinct problems. A type of motor which may prove admirably adapted for the steady conversion of electrical into mechanical energy (at the rate perhaps of some hundreds of horse-power) might easily become valueless if built upon a smaller scale and set to do intermittent work under varying conditions. The continuous-current motor has long furnished an adequate solution of the distributing problem (though it still remains absolutely without illustration in this country). But whilst little has been said about it, the fact is generally recognised that for the transmission and conversion of energy upon the larger scale with continuous currents an upward limit is soon imposed by reason of the very serious difficulties of dealing with high tension in such machines. So far as the motor itself is concerned, these difficulties make themselves apparent with continuous-current machinery at a far earlier stage than is the case with alternators, and we do not hesitate to express the opinion that if ever Sir William Thomson's vision of the utilisation of the Falls of Niagara is realised it will be by means of the alternate-current motor. We say this in spite of M. Leblanc's confident assertion that the synchronising motor (of the type identical with the generator) is necessarily inefficient. It is true that the maintenance of cophasial synchronism necessarily demands a certain expenditure of energy—it is also true that this is wasted as heat in the coils of the armature, but in the absence of direct experimental evidence it would seem that M. Leblanc is somewhat rash in asserting that this loss is necessarily so great as to seriously impair the efficiency of the system. We anticipate that Mr. Mordey will before long be in a position to throw some light upon this important point.

Since the above notes were written, we learn from the pages of the *Comptes Rendus* that M. Leblanc has himself invented and constructed an alternating motor of a novel and highly remarkable type. On another page will be found a full translation of the brief memoir in which the inventor has submitted his solution of the problem to the French Academy. It must be admitted that the absence of diagrams and the somewhat complex character of the design renders the description not altogether as intelligible as could be wished. It may be well, therefore, that we should for the present abstain from any attempt at criticism, but it is noteworthy that, in laying down the general principle that an efficient motor must have the smallest possible self-induction, the Author is (perhaps un-

Digitized by Google

awares) following straight in the footsteps of Mr. Mordey. M. Leblanc does not, however, content himself with a design in which the mere absence of iron and the proportioning of the parts renders the armature self-induction a minimum—he goes a step further, and seeks to cancel the self-induced field by introducing at the right moment a flux of lines in the reverse direction. The action, if we have correctly apprehended M. Leblanc's project, is similar to the well-known effect which takes place in the coils of a continuous-current armature whilst they are short-circuited by the brush, and when the lead is such that the self-induced E.M.F. is just balanced by the induction of the field, in which case we get no sparking. In M. Leblanc's motor this effect is reproduced upon a larger scale, but whether it is wise or necessary for this purpose to rotate the brushes as well as the commutator is rather open to question.

Our New York correspondent, referring to the question of laminated armature cores, points out that this device was described by M. A. Pellerin in the *Comptes Rendus* (Vol. LXXVII., No. 9) as long ago as 1873. We may add that a translation of the note referred to was published in the *Telegraphic Journal* of the same year (Vol. I., p. 271) in the following terms:—

"The Siemens' bobbin has a great inconvenience, that it gives rise, in the machines in which it is employed, to a considerable development of heat, and consequently a corresponding loss of work. It is possible that the origin of a greater part of this heat is in the induction currents developed by the movement of the mass of metal forming the core of the bobbin. We avoid the production of these currents *by forming the core of discs of soft iron insulated.* The assemblage of these discs in a sufficiently solid mass is not an insurmountable difficulty."

In the light of the above quotation, there would seem to be very little chance of establishing the Edison patent of six years later.

In our recent reference to the existence of this Edison patent, and the probability of its coming prominently under notice, we need scarcely assure our readers that we had good and sufficient ground for saying what we did. A contemporary journal not happening to be in possession of our information, first charged us with raising a false alarm, and then proceeded to beg the owners of the patent, if they had any such intention, to abandon the idea of its enforcement. We take a different view of this question. If a firm or company find themselves in possession of any patent which they have reason to believe of value, we cannot conceive upon what possible ground they should be expected to forego the advantage even if it is obtained wholly at the cost of their competitors. To a business man such a suggestion must appear to verge on the childish. At the same time we fully recognise that the position of those who have infringed a patent, possibly for years, in ignorance of its existence would become very hard indeed if an attempt were made to recover royalties from the commencement; and this is a course which no firm could adopt without distinct loss of reputation. It seems to us that in such a case justice would be met—supposing the patent could be sustained by the payment of a comparatively small tribute. We are none the less pleased, as regards the particular case alluded to, above to be now able to publish an anticipation which on the face of it would seem fatal to any subsequent claim.

The Council of the Institution of Electrical Engineers is inviting the opinion of its members on the long-vexed question connected with the nomination and election of officers. So far as it goes the statement put forward by the Council is fair enough; but it fails to appreciate at their full weight the objections that have been raised to the "old" system, and which, indeed, perhaps equally apply to the "new." These objections are—firstly, that an insufficient time is allowed to challenge the nomination of the Council, supposing the members wish to exercise their undoubted right to do so; and secondly, that, waiving this right, they are still required to go through the elaborate and meaningless function of an election.

One of the alleged disadvantages of the present system of nomination is that it deprives the Council of the services of some very desirable candidates, who absolutely decline to be put in competition. In other words they are willing to be nominated by the Council, but refuse to be elected by the members. If this feeling prevails generally among "men of high scientific attainments" it goes to prove that the election system is altogether a wrong system, and we are not disposed to dispute the proposition. What we do dispute is the expediency of keeping up the pretence when the reality has been frankly abandoned.

Despite the marvellous success of the phonograph as a piece of mechanism, persons have been known to raise the question whether its practical every-day utility is likely after all to prove of much importance, and the long delay in launching the venture on the commercial world lends some additional weight to such forebodings. We are therefore happy to signalise in our columns the fact that M. Firmin Larroque has indicated a field of usefulness for the phonograph, whose importance to the engineering world it is difficult to over-estimate, though, unhappily, the extent of the probable demand for the apparatus will not be much enhanced. It is admitted that the life of an iron or steel bridge cannot be indefinitely prolonged, and yet engineers do not possess any completely satisfactory method of determining the actual condition of these important structures. So long as no actual deformation has taken place, the iron may here or there be assuming a crystalline condition, or may be seriously oxidised underneath the coating of paint, and yet the extent of the evil can easily remain undiscovered. M. Larroque proposes a remedy. His suggestion is to employ the phonograph in connection with a microphone and telephone to register the nature of the vibrations of the bridge as a whole or in sections under a rolling load, and to preserve the record for comparison with subsequent tests carried on at regular intervals. The direct comparison of two phonographic records cannot be carried out with sufficient accuracy, M. Larroque, therefore, employs an optical method, and reflects a beam of light from the vibrating plate, after the manner of the well-known Lissajou's figures. It would, of course, be

Digitized by Google

necessary to secure a long series of such records before the results would be capable of complete interpretation, but it certainly seems quite possible by such means to obtain reliable indications of a change in the molecular structure of the material.

In our last issue we unwittingly did some injustice to M. Hermite in speaking of his electrolytic sewage disinfectant process as subsequent in date to that of Mr. Webster. On a comparison of the English patents we find that the specifications were filed at nearly the same period, but that M. Hermite's was actually the first of the two to be accepted and published. We hope shortly to give some further details of the Hermite process.

Truro.—It is stated that the Truro Gas Company have applied to the Board of Trade for a Provisional Order to enable them to light the town and its vicinity by electricity.

Stockton.—The Electric Light and Power Corporation and the Northern House-to-House Electricity Company have given notice of their intention to apply for Provisional Orders.

Personal. — The Professorship of Civil Engineering and Mechanics in the University of Glasgow is likely to be vacant by the resignation of Prof. James Thomson on account of ill-health.

The International Congress.—The first meeting of the Congrès International des Electriciens will take place at 10 a.m. on Saturday, August 24th, in the Salle des Congrès et Conférences at the Trocadéro.

The Electric Lighting of the Japanese Houses of Parliament.—A contract for 350 electric lights to illuminate the Japan House of Parliament has been placed with the Tokyo Electric Light Company.

Electrical Tenders.—It will be seen by our advertisement columns that the London County Council invites tenders for making perfect and maintaining for one year all the wires and apparatus connected with the London Fire Brigade.

Engineering Courses.—The 1889-90 Session of University College, Nottingham, begins on October 7th, and special facilities are offered to students in electrical engineering. Further particulars with respect to the courses will be found in our advertisement columns.

Errata.—In paragraph three of Mr. J. D. F. Andrews' letter, which we published last week, the word "charges" should read "changes." "Magnetic leads," in the sixth paragraph, should read "magnetic blades"; and "leaders," in the seventh paragraph, should read "blades."

Airdrie.—At its monthly meeting, held on Thursday last week, the Council unanimously adopted a recommendation by the Lighting Committee to the effect that the Council should apply for a Provisional Order empowering them to light the burgh with electricity on their own account.

Tyldesley.—At the last meeting of the Tyldesley Local Board notice was received from an electric lighting company that they intended to apply to Parliament for a Provisional Order for the district. The Clerk was instructed to inform the company's solicitors that the Board intended to oppose the application.

Coventry.—At a meeting of the Town Council last week the Midland House-to-House Electricity Company gave notice of an intended application for a Provisional Order. The Council decided to oppose the application. Alderman Gulson said the Corporation having the gas monopoly, it would be absurd on their part to encourage a rival of that monopoly.

Wrexham.—At a recent meeting of the Wrexham Town Council a letter was read from Mr. F. Vaughan Hughes, of Chester, who wrote on behalf of the Wrexham and District Electric Supply Company to inform the Council that they intended to apply for a Provisional Order. Mr. Hughes said it was a local company and was supported by local people.

The Priestman Oil Engine.—We learn that the Northern Lighthouse Board have adopted the Priestman Oil Engines for blowing fog signals in preference to steam or gas engines. These engines are evidently well suited for such a purpose, no chimney being required as in the case of a steam engine, and gas being seldom available unless special works are erected.

Lancashire County Council.—At the last meeting of the Lancashire County Council the Clerk reported the receipt of a notice of intended application to Parliament by the Anglo-American Brush Corporation for a Provisional Order. The area of the proposed operations was Didsbury, Withington, Heaton Norris and Reddish Local Board Districts. The matter was referred to the Parliamentary Committee.

Tours.—The town of Tours, which was one of the first provincial towns of France to have a central lighting station, is the first to have luminous fountains, two of which have been installed on the Place du Palais. The electrical arrangements were entrusted to the Compagnie Internationale d'Éclairage Électrique, and the four 40-ampere arcs with horizontal carbons are run off alternate-current transformers.

The Glasgow District Telephone Directory.—The 1889-90 edition of this useful publication has attained the respectable dimensions of over 300 pages. The subscribers, in addition to being arranged alphabetically under their respective exchanges, are also classified according to professions and trades. The Directory contains full particulars with regard to rates of subscription, trunk wire tariff, the erection of private wires, as well as other useful information.

The Electric Launches on the Thames.—The Prince of Wales ran up the river a few days ago in Messrs. Immisch and Co.'s electric launch, the "Viscountess Bury." Starting from Kew Bridge for Sunbury, a visit was paid to Platt's Eyot, where the above-mentioned firm has a charging station. An electric torpedo boat in course of completion attracted some attention, and after a trip in several of the smaller launches the party proceeded down the river, landing at Chelsea.

Presentation to Mr. Mackay.—The staff of the Commercial Cable Company on Christmas Day last presented Mr. John W. Mackay with a magnificent silver piece, as a token of their regard for him. It was accompanied by an appropriate address. Since then the address has been engrossed in a very beautiful album and signed by every member of the staff, and a few weeks back a committee of about a dozen waited upon Mr. Mackay and made the formal presentation.

Proposed Electric Railway for Eastbourne.—The Mayor of Eastbourne has just received a requisition, signed by a number of the leading business men of the town, requesting that a meeting may be called at an early date at the Town Hall to allow of the preliminary consideration of the proposed electric railway along the sea front from the Wish Tower to Beachy Head, by way of Holywell Rocks, a distance of nearly two miles. The Mayor will next week convene the meeting desired.

Mayfield and Co.'s Catalogue.—The greater portion of this catalogue is devoted to laboratory and lecture apparatus, and contains a very complete list of electroscopes, electrometers, Ruhmkoff coils, vacuum tubes, &c. The rest of the catalogue relates to domestic electrical apparatus, and includes dynamos, accumulators, gas engines, bells, batteries, and switches. Amongst other things we notice an improved burglar alarm, a double-lock indicator, and some handy direct-reading pocket ammeters and voltmeters.

The Telephone in Berlin.—The following table, showing the number of telephone subscribers in Berlin at different dates, gives an idea of the rapid development of the telephone service in that capital:—

Date.	Subscribers.	Date.	Subscribers.
April 1, 1881.....	50	End of 1885.....	4,324
End of 1881.....	458	,, 1886.....	5,507
,, 1882.....	1,069	,, 1887.....	6,954
,, 1883.....	1,625	,, 1888.....	9,199
,, 1884.....	2,412	April 1, 1889.....	9,534

Present time upwards of 10,000 subscribers.

Digitized by Google

A Meteorological Congress.—The Société Meteorologique de France has arranged a Congress, which is to be held in Paris from the 19th to the 25th September. The programme contains the following amongst other questions for discussion:—Magnetism: The Relation between Magnetic Phenomena and Earthquakes; the Study of Earth Currents; Magnetic Observations at Sea. Electricity: The Methods of Observing Atmospheric Electricity; the Relations between Electricity and other Meteorological Elements; the Aurora.

Cooking by Electricity.—The Hotel Bernina, at Samaden, has for some time been lighted with electricity, power being supplied by a waterfall. As during the day this power is not required for lighting, and is therefore running to waste, the proprietor of the hotel has hit upon the idea of utilising the current for cooking when it is not required for lighting, and an experimental cooking apparatus has been constructed. This contains German silver resistance coils, which are brought to a red heat by the current, and it has been found possible to perform all the ordinary cooking operations in a range fitted with a series of such coils.

Chelmsford.—It is hoped that Messrs. Crompton and Co. will be able to commence their contract for the lighting of the town some time in September. As will be remembered, the main streets are to be lighted by eighteen 1,000 candle-power arcs and the remaining portions of the town by two hundred 32 candle-power incandescents. The incandescent lamps are to be fixed in lanterns, which will hang from brackets about 15 to 20ft. high. The arc lamps will be suspended between poles, about 25ft. high. The wires will be carried overhead at the height of about 25ft. The generating station is being built under the new offices of the company at the works, and the foundation for the machines has been laid some time. The lighting will be carried out by alternate-current transformers.

The Telephone in Italy.—According to a Bill at present before the Italian Parliament, telephone exchanges are only to be worked under Government concessions or by the Government itself. The maximum annual subscription for town service is fixed at 200fr. for all instruments within three kilometres from the exchange. For distances beyond this 3fr. extra for every 100 metres for the first two kilometres, and 2fr. for every 400 metres over five kilometres from the exchange. Government, Provincial, and Communal authorities are to have a rebate of 30 per cent. The maximum tariff for inter-urban communication is to be 1fr. 50c. for every five minutes' conversation over short wires, and 2fr. beyond a distance of 100 kilometres. The Government may temporarily suspend or restrict the telephonic service for reasons of public safety.

The Electrolytic Preparation of Iodine.—Messrs. Parker and Robinson have brought out a process of precipitating iodine from its metallic compounds by electrolysis. The vat containing the electrolyte is divided by a porous partition, one division containing the anode of carbon or platinum, and the other the cathode of iron. The anode is surrounded by an aqueous solution of some metallic compound of iodine, to which is added either hydrochloric or sulphuric acid. The cathode is surrounded by an alkaline solution. The current density usually employed is ·125 ampere per square inch of plate. Under the action of the current the iodide is split up, hydroiodic and iodic acid being formed in succession. These acids finally give up their iodine, which is deposited at the anode, in virtue of its almost complete insolubility in water. It is collected by decantation and purified in the ordinary way.

High-Tension Currents.—In the present turmoil in this country on the question of safety as between the continuous and alternating currents, perhaps the most striking aspect of this Electrical Saurian, says the *Electrical Review* of New York, is the calmness with which enormous pressures are discussed by its English projectors. Our alternating-current systems are, we believe, mostly operated at a pressure of 1,000 volts, though some of them double that figure. But here comes the slow and conservative English capitalist and puts his money into a stupendous plant which is to make a total eclipse of our largest stations, and this is to be all done at the tremendous pressure of 10,000 volts! And this is not the scheme of some visionary feather-weight, nor the attempt of any electrical Icarus to reach the sun of notoriety, but it is the deliberate decision of some of England's foremost and most practical electrical engineers.

An Incandescent Lamp Slide Rule.—The Edison-Swan Company have brought out a slide rule, designed by Dr. J. A. Fleming, for performing with great readiness any of the usual calculations with regard to incandescent lamps. It consists of a rule carrying four similar scales, marked respectively (1) Amperes; (2) Volts; (3) Candle-power; (4) Watts per candle-power. Two of these scales, viz., the first and fourth, are engraved on the rule, and two, viz., the second and third, on the slide. There is also a brass slider having a reading point. The calculations which may be done by this rule are as follows:—(1) Given the current through a lamp, the terminal volts, and the candle-power, find the Watts per candle-power. (2) Given the Watts per candle-power and the candle-power, find the current corresponding to any voltage. (3) Given the volts and the current, find the hot resistance of the lamp. (4) Given the volts and current when the lamp is burning at normal brilliancy, find the candle-power approximately. This ingenious slide rule will no doubt be of great use to all those engaged in incandescent lighting.

The Melipuli-Punta-Arenas Cable.—The Chilian Government have just issued a decree relating to the laying of a new submarine cable between Melipuli and Punta-Arenas. All tenders must be in the hands of the Minister of the Interior at Santiago by the 30th November next. Other things being equal the contract will be awarded to whoever submits the best specimen of cable, engages to lay the cable within the shortest period, and gives the most reliable guarantee for the execution of the contract. The contractor will be responsible for the proper working of the cable for one year after the completion of the work. All tenders must be accompanied by a deposit of 5,000 pesos (£1,000). The cable is to start from Melipuli (Puerto-Moutt), and to touch at Palena, at the mouth of the river Buta-Palena; it will run thence to Port Otway, across the Gulf of Las Penas to Munoz-Gamero, thence through the Straits of Magellan to Punta-Arenas (Sandy Point). When laid this cable should bring a good deal of traffic to the West Coast of America Company.

Electricity in Powder Mills.—The German technical journals have recently published some instructions as to the precautions which ought to be observed in powder mills to prevent explosions from electrical causes. The necessity for some such precautions is clearly shown by recent explosions, several of which are attributable to electricity. In a large powder mill, in Germany, an explosion lately occurred in the press room. A workman engaged in pressing powder into cakes between sheets of ebonite, left his work during a thunderstorm. When the storm was over he loosened the press, and on putting out his hand to remove the powder, a spark 4in. long went to earth through his body, igniting the powder, and killing the man. The employment of insulating substances, such as gutta percha, ebonite, &c., is therefore considered as likely to lead to accidents. In the powder mill of Herr W. Gutler the sulphur crushing machines are all put to earth, and since this precaution has been taken there has been no trouble from the mysterious explosions which had previously proved so troublesome.

City of London and Southwark Subway.—The directors of this company, in their report, state that the whole of the tunnels from the City to a point considerably beyond the Kennington Oval Station, a distance of about 2¾ miles, have been completed, and the main underground works at the King William-street, Great Dover-street and Stockwell Stations have also been finished, and those at the other three stations are in a forward state. The station buildings on the surface at Great Dover-street and the Elephant and Castle have been commenced, and the necessary alterations of the buildings at King William-street to fit them for the City station are nearly completed. A short piece of tunnelling about 250 yards in length, between the Oval and the terminus at Stockwell, is still incomplete, owing to the existence of a wet bed of gravel through which the work is being carried on under air pressure, a slow and tedious process. The rails are now laid in the tunnels between King

Digitized by Google

William-street and Great Dover-street, and an experimental train worked by electricity is nearly ready for trial on this section.

A Peculiar Earth—A short while ago it was noticed, at Boston, U.S., that the horses were very uneasy when passing over an area of, say, 10ft. square in the granite pavement of Boylston street. An investigation by the Edison people seemed to show no trouble, and everything went right for ten days or more, when, during a rain-storm, the same action of the horses was noticed. Upon digging down to the wires, which were embedded in a bitumen compound, a spot was found where the box was eaten through. The insulation of the negative wire was found to be destroyed, and as the neutral is earthed in the station there was a leak sufficient to affect horses as well as men. Chemical examination of the insulation at the fault showed that it was orignally concentrated lye, which had become partly converted into caustic soda by water, and that the action of the currents had, by electrolysis, formed a considerable quantity of metallic sodium throughout the mass. It is supposed that in some way a piece of lye tumbled into the kettle in which the insulating compound was made and was not noticed. Hence the trouble.

Kingston-on-Thames.—A private conference of the representatives of the various local authorities in the district took place at the Kingston Town Hall on Monday last week to consider whether united action could not be taken with reference to the applications about to be made by various electric lighting companies for powers to supply the neighbourhood with the electric light. It was resolved to oppose the applications of the companies, with a view to the local bodies obtaining powers themselves to supply the light; and the meeting was adjourned for a fortnight to decide upon what steps should be taken. Later on in the week a long report on the subject was presented by the General Purposes Committee of the Kingston Town Council, in which it was stated that it was clearly the duty of the Corporation to refuse to give consent to any company unless it possessed ample capital to supply the whole area it sought to acquire, and the report concluded by recommending that the neighbouring local authorities should unite for the supply of the district generally.—The report was adopted unanimously.

An Electric Census Machine.—Electricity is to be put to a new use in the forthcoming census in the United States. The census collector will call with his printed blank, and answers to questions will be written in the usual way. These sheets will then be placed before a person who operates a machine which may be likened to a typewriter, except that, instead of the usual ink marks on paper, small round holes are punched in a card. The cards, one for each person, are about 6½ inches in length by 3 inches in width, and the particular position of hole in a card indicates an answer to some of the questions in the printed blank. These cards, when punched, are placed one at a time in a sort of press, and a lever operated by hand is brought down, when a series of pins are brought against the card. Whenever a hole has been punched in a card, the corresponding pin passes through into a mercury cup beneath completing an electric circuit. These circuits, one for every hole, include a large number of counters which operate electrically, and which add upon their dials all items of the same kind upon the same dials. For instance, all white men are counted upon a dial marked "white males;" all business or professional people upon dials which indicate their particular business or profession. The cards, as they leave the press, are all sorted by means of an electrical sorting device, whereby they may be separated into groups or States of the Union.

Bedford.—The Bedford Electric Lighting Company, in offering to undertake the establishment of the electric light in Bedford, submitted for the consideration of the Corporation the following propositions suggested by Sir Henry Mance:—

"In consideration of the Bedford Corporation affording all reasonable facilities to the company for their operations and, as far as possible, securing to them a monopoly so long as the service is efficiently performed by the Bedford Electric Light Company in accordance with the stipulated conditions, the latter agree to give the Bedford Corporation every five years the option (on giving one year's notice) of purchasing the undertaking at a price not exceeding twenty years' purchase of the profits, the profits to be estimated on the results of the last year's working, or an average of the last five years, whichever may be most favourable to the company. In calculating the profits any gains derived from contracts for public lighting would be excluded. It is, however, provided that should the company not have paid an average of 5 per cent. on its share capital during the time it may have been in operation, the purchase money paid shall not be less than the par value of the shares and debentures, together with such sums as may enable the directors to pay 5 per cent. on the share capital from the commencement. If desired, the company would allow one director to be nominated by the Corporation; they would agree to commence operations within six months, and undertake to be in a position to light the principal thoroughfares before the end of the first year. On reasonable notice being given, they undertake to extend the arrangements for private supply to outlying districts as soon as 25 per cent. of the residents require the light. All posts required for public lighting to be erected by the Corporation. The price to be charged for the light *not to exceed*: For any number of arc lights (not less than 30) of 1,000 candles nominal for public lighting, 3d. per hour each; arc lights for private use of similar power 6d., per hour each; incandescent lamps supplied by meter per Board of Trade unit, 10d. per unit. In the event of the Corporation preferring not to enter into any special arrangement which would enable them to acquire the undertaking every five years, the company were quite prepared to commence operations on receipt of permission to cross the river with cables or the streets with wires, as is done with the telephone wires at present, it being also understood that permission to lay the wires underground, should such a course be eventually necessary, would be given when consistent with public convenience."

Electricity on War Ships.—At a recent meeting of the Naval Institute in Annapolis, Mr. S. D. Greene, electrician of the Sprague Company, read an interesting Paper entitled "Electricity on board War Ships." The opening remarks were devoted to the question, Who should have charge of the laying out and installation of the electric plant for a ship? At present each bureau in the United States Navy department has charge of the apparatus belonging to its department on board ship. Such arrangement would obviously be most unsatisfactory in the case of the electric plants, and Mr. Greene dwelt with a deal of force upon the necessity of having all the electric apparatus under one head, both in its designing and in its practical operation. The dynamo room, where a large plant is used, had now become one of the vitals of the ship, and hence must be afforded all the protection that the type of vessel allows. Importance was attached to the necessity of having all engines and dynamos duplicates of each other. Under the heading of the wiring and lamps several suggestions were made, based on experience gained ashore. The use of a lead covering on the wire, to act as a mechanical protection, was condemned on account of its liability to break when handling. As a substitute it was suggested to use either an armoured wire, such as is used in submarine work, or else a plain, bare wire, run in a continuous slate or porcelain trough. The various classes of work done by the auxiliary engines of a ship were next enumerated in detail, and it was shown how motors could be used to advantage instead of steam or hydraulic machinery in each case, and what type of motor was best suited for the particular work in question. Attention was drawn to the fact that an ammunition hoist had recently been put on board the "Atalana," operated by a motor, and that one of the gun carriages of the "Chicago" was being fitted with a training motor and an elevator motor. These were the first two applications of their kind. A contrast was drawn between the complicated task of running steam pipes all over the ship, and the easy, simple operation of running electric wires. The advisability of increasing the number of search lights on the new American war-ships was shown, together with the use of these lights for long-distance signalling. One of the latest electrical devices described was the new range finder invented by Lieutenant Fiske. The use of firing circuits for firing the main battery of a ship was strongly argued. In action, with the ship rolling, the gun captain must be able to fire his gun the instant the sights fall on the object aimed at, and electricity is the best known agent to accomplish this. In addition, there are times when a commanding officer will himself want to fire his whole battery simultaneously, and he can do so best by pressing an electric button.

ON THE DISTRIBUTION OF ENERGY BY MEANS OF ALTERNATING CURRENTS.*

BY M. LEBLANC.

(*Continued from page 321.*)

Mr. Mordey's Motor.—Mr. Mordey has some time since designed an alternate-current motor in which any suitable continuous-current type of machine may be employed. It is, however, necessary that the field magnets should be built up of laminated iron. This is not because the alternate current itself is used to excite the field, but for a reason which will presently appear. In addition to the usual commutator and collecting brushes, the machine is provided with a second commutator, consisting essentially of the old-fashioned halved-ring—the two-part commutator as it is sometimes called. The two halves of this ring are connected (through suitable collecting rings and another set of brushes) with the brushes which bear upon the commutator belonging to the motor itself. The brushes which bear upon the halved-ring commutator are those which convey the alternating current. It will now be seen that if the motor run at a speed corresponding to the periodic time, the alternating current, after having traversed the first commutator, will have its two opposite phases brought into the same direction. In practice we could not conveniently make use of a mere two-part commutator, as this would demand a tremendously high velocity. We may, however, employ any convenient number of segments connected alternately in pairs.

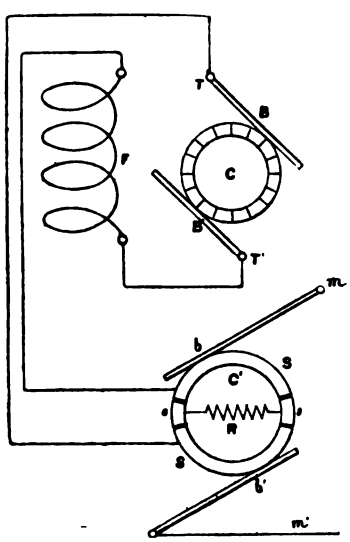

FIG. 5.

The action will be understood from the above diagram (Fig. 5):—C is the commutator of the continuous-current dynamo with its field-magnets in series, and C_1 is the "two-part" commutator of which the segments S S are connected directly with the brushes T T of the motor. The connection is made by a separate pair of brushes and collecting rings, which are not shown in the diagram. The alternate current is led into the commutator from the terminals *m m'* by the brushes *b b'*. Between the segments S S are two smaller segments, *s s*, which are connected by a resistance, R; this is to avoid short-circuiting the mains at the moment of reversal. It will now be seen that when the motor is running, until it has acquired its normal speed, the field-magnets F will receive an alternating-current; but as the velocity increases the commutator C_1 gradually transforms this in the motor circuit into a current uniform as regards direction.

In a motor so designed the value of the coefficient of self-induction appears to diminish as the speed increases; it attains a minimum when the alternating current has been fully commutated, and from this point it again increases as the speed rises. The torque at first increases with the speed, attains a maximum at the point of normal commutation, and then again diminishes. It is easy to see that this arrangement possesses several practical advantages. In the first place it is self-starting. Secondly, the self-induction of the system being high at the outset we have no need to close the circuit upon an intermediary resistance. The speed gradually accelerates, but it cannot exceed (to more than a slight extent) the normal value at which the commutation is perfect, for if it does the self-induction increases, the current is choked off, and the torque diminishes. Hence also the machine can never "race," and the load may be varied from zero up to the point at which its maximum torque is counterbalanced without sensibly varying the speed.

This machine would seem therefore to furnish an excellent solution of the problem of the alternate-current motor, but unhappily, such as it is, it presents all the disadvantages inseparable from the "redressed" current; and we are thus, so far as the continuous-current motor is concerned, little better off than we were in the days before Gramme taught us how to obtain a current *quasi*-continuous in form. The two-part commutator is, moreover, a feature which cannot be wholly commended. In order to avoid difficulties of sparking and of the nice adjustment of the brushes, Mr. Mordey resorts to the device of interposing two short segments, *s s* (Fig. 5), connected together by a resistance, R. This device avoids the short-circuiting of either generator or motor at the moment when the brushes change segments; but, on the other hand, the circuit of the motor will now remain open so long as the brushes rest upon the intervening segments, so that it is open to question if the remedy be not worse than the disease. The energy lost in the resistance R is not of much consequence, because the alternating current is at that moment passing through zero value.

From what has been already said, we may arrive at the following conclusions:—

1. An ordinary alternator employed as a motor possesses the important advantage that the additional resistance and impedance introduced into the circuit of the generator is small. But it must be separately excited, and its synchronism cannot be maintained without a certain loss of energy, which is dissipated as heat in the armature. This system is not therefore capable of rendering a high efficiency.*

2. The machines of the type of the Tesla and the Elihu Thomson motor possess several very interesting features, some of which are practically advantageous. But the effects of self-induction which occur considerably augment their impedance, and render them unsuitable for the transmission of large forces.

3. In Mr. Mordey's machine the self-induction effects are positively advantageous as regards the development of the torque on the shaft of the motor, but, nevertheless, we have to employ what is actually an *intermittent* as well as a varying current in the circuit of the motor, and we cannot therefore expect to obtain results comparable with those of a continuous-current.

(*To be continued.*)

* Abstracted from *La Lumière Electrique*.

PARLIAMENTARY INTELLIGENCE.

The Select Committee of the House of Lords on the Metropolitan Electric Lighting Schemes.

TUESDAY, AUGUST 6.

The Select Committee of the House of Lords appointed to consider the Bills for confirming Provisional Orders granted by the Board of Trade for supplying electric light to the metropolis met to-day. The chairman is the Earl of Limerick, the other members of the Committee being Lords Lauderdale, Lindsay, Ellesmere, and Clavenagh.

Mr. PEMBER, Q.C. (with whom were Mr. Moulton, Q.C., and Mr. Loyd), addressed the Committee on behalf of the London Electric Supply Corporation. After describing the system proposed to be adopted by the Corporation, he referred to the opponents, and challenged the *locus standi* of the St. James's and Pall Mall Electric Light Company (Limited), and of the City of Westminster Electrical Syndicate (Limited).

* It is permissible to question whether, in the absence of direct experimental evidence with modern machines, this decision is as yet wholly justifiable.—ED. *E.*

Digitized by Google

The latter case was argued first, Mr. LITTLER, Q.C., contending for the Syndicate that even the London Supply Corporation had no right to be there, as they had not the consent of the local authority, and the special report required by the Act where the Board of Trade consider that such consent should be dispensed had not been made.

Mr. PEMBER replied, and the Committee, after deliberation, held that the *locus standi* of the Syndicate had been established. The objection to the locus of the St. James's and Pall Mall Company was not proceeded with.

The EARL OF CRAWFORD AND BALCARRES was then called, and in reply to Mr. LOYD, said they were supplying about 30,000 lights at the present time, about 6,000 being in St. James's. They had been supplying current in St. James's for a considerable time. With regard to the St. James's Company, the Board of Trade had held an inquiry in accordance with the Act, and the Inspector had recommended that there should be two companies in the district, and by that decision his company claimed to abide. He was against any monopoly. The St. James's Company would not be affected except that they would not get so many customers. That company had no mains laid down at the time of the inquiry, but they had been pushing on with great activity since. He first became aware of the City of Westminster Syndicate when they petitioned the House of Lords. He ought to have known more about them, but he was under the impression that the works used by them were the works of another company. They had received a very large number of requisitions to supply in Westminster, especially about the region of Victoria-street.

Cross-examined by Mr. BIDDER, who appeared for the St. James's Company: He considered they had been very modest, as their original demands had been reduced by one-half. Their capital of a million and a-quarter would not provide all the works to adequately and fully supply the whole of their district. On a large scale he believed they could put down and distribute light at an expenditure of about £1 per head, so that it would require about double their present capital. With regard to the compulsory streets, he would rather not have had them, but in most cases they were streets where he would have gone of his own accord. It was stated at the inquiry that the alternating system was not suitable for motors; but the contrary had since been demonstrated. In order to stave off Parliamentary opposition they had agreed with the Chelsea Company not to go into certain streets in Chelsea except upon requisition. He could not enter into a similar agreement with the St. James's.

Cross-examined by Mr. BATTEN, on behalf of the City of Westminster Syndicate: The Board of Trade has already taken away a large portion of his area, and he could not consent to give up more.

Re-examined by Mr. LOYD: There were companies in competition with them over the whole of the area north of the Thames. There was nobody in competition with them on the south of the river; but he was given to understand that a good number of notices had been put in on the south of the river for next year. With the plant on order they would be able to supply about 450,000 lights. If the engines were ready, and capable of giving out current at once for 400,000 lights, it would be certainly impossible for the trade to wire houses sufficient to receive that current under six or eight months. Their plant was more than sufficient to supply the demand at the present time, or even within the next three or four months. The Deptford station was intentionally so planned as to admit of duplicating and reduplicating the plant. Compulsory streets having been mapped out by the Board of Trade, the requisition was the common-sense way of making the supply follow the demand as to the remainder of the district. Since the inquiry there had been a public demonstration by the Brush Company that it was possible to work motors by alternating currents.

Major MARINDIN, R.E., was then called.

Mr. BIDDER objected that it would be irregular to examine Major Marindin upon his report, which was his judicial utterance.

The Committee having deliberated upon this point,

The CHAIRMAN said: The Committee are of opinion that it is quite competent to call Major Marindin. To the Witness: If you think any question put to you would fetter the examinations you may have to hold hereafter, if you would bring that point before the Committee, the Committee would consider whether the question should be put.

Major MARINDIN was then examined by Mr. Loyd. He said that he considered districting was necessary where there were two alternating companies in the same district. Where a parish agreed to the entrance of electric lighting companies, he thought, for the present at any rate, they should be limited to two, for reasons given in his report; and where there were two companies he thought it desirable (because the evidence before him was to the effect that there was no motor for alternating currents) that one of those companies should be alternating and one direct. Between two alternating companies he thought it better to district than to allow two alternating current systems to occupy the same area, which would possibly have the effect of excluding the direct supply. He had nothing to do with the St. James's Company. They had their license and were in the St. James's area as a direct company. He did not think it desirable to put two more companies in that area, and he had therefore to elect between the Metropolitan and the London. His reason for selecting the London was this:—In districting between the two companies, he thought it necessary to take away part of the area which the London Company were then supplying. The Metropolitan having agreed with the Marylebone people, he thought it necessary to leave that parish to the Metropolitan. He had it before him that the London was supplying in Marylebone and in St. James's very largely by means of overhead wires. He thought it was very desirable that overhead wires should be abolished, and therefore, having left Marylebone to the Metropolitan, he allotted St. James's to the London, putting them under the obligation to remove the whole of their overhead wires within a certain time. He did not think it would be within the powers of the Board of Trade to grant a mere way-leave through a parish; and that was one reason he had for recommending the Board to schedule compulsory streets. He did not think it desirable that a part of a district should be used simply as a means of getting to another; any company going through a parish should be put under an obligation to supply. He thought there should be continuity of area, and that was one reason for giving the united parishes of St. Margaret's and St. John's to the London. Another was that the London had their generating station south of the Thames. They could get across, it was perfectly true, by agreement with the railway company, but he thought it better that they should have an alternative route by which they could reach their district on this side of the Thames, without being absolutely dependent upon agreements with the railway companies. On a railway, for instance, the route might be broken by a run off.

Cross-examined by Mr. BIDDER, Q.C.: You have acted under the belief that the Board of Trade had no power to grant to an electric light company a way-leave through a district which is not part of their own district?—I believe that they have only power to grant leave to break up streets in the area of supply; and apart from that I consider that where they do come through they should be put under obligations.

That is implied in what you say in your report: "It is in the case of St. Mary, Lambeth, essential to the continuity of the London Company's area that this company should have the means of passing through the northern end of the parish." If, in fact, a company submits a scheme to you which has a generating station at one end of London and the district of supply at the other, in order to effectuate their wishes you feel it necessary to give them all the intervening district, or at least so much as will enable them to lay their pipes along?—I do not admit that is quite the case. They had a very large district to get to, and it is a very small piece it goes through.

The principle on which you dealt with this company was that Deptford Generating Station being down the river, and the place to be aimed at being in the neighbourhood of Chelsea and so on, it was necessary to put them in those intermediate districts of Bermondsey, Rotherhithe, and so on, to enable them to find a road?—No, the districts of Bermondsey, Rotherhithe, and so on, as you put it, wished to have them; as did also the district of St. George's, Hanover-square. Those districts which wanted to have them formed a very large proportion of the district of supply. A much smaller proportion did not consent to their coming through. If the northern part of the parish of Lambeth had not intervened between the districts which wanted to have this company I would not have put it in. Two districts have been added to the area of this company to make the area continuous.

You might have acted on another principle; this company, being essentially a company contemplating a generating station on the south side of the river, might just as well have confined their operations to the south side of the river?—No; I do not think so, because they were actually supplying a very large proportion of the north side of the river at the time.

You say there ought to be two companies everywhere?—No; I think it is desirable that there should be two companies. I think competition is desirable, but I do not say everywhere. I have stated in my report that where the local authority did not wish to have a company in, then I thought only one should be allowed in.

As a matter of fact the local authority of St. James's appeared before you protesting against the second company coming in?—They appeared before me to oppose. At the same time the representative of the vestries said that provided they would consent to come in on the same terms as the other company he would let them come in. The reason for that, as given in his evidence, was that they were already supplying largely in the parish. The Vestry said that they would rather have the Metropolitan.

You stated that the Metropolitan had agreed with Marylebone, so that it was necessary to turn out the London?—No; in districting between the two they were to allot Marylebone to the Metropolitan.

Your reason for not turning the London out of St. James's is that they have got overhead wires, which you regard as a nuisance, and you do not turn them out in order to be in a position to get rid of overhead wires?—I thought you could not fairly insist upon their not taking down the whole of their overhead wires if we took their whole business away from them.

You are aware that by the Act of last year the consent of the Vestry was necessary unless the Board of Trade thought it should be dispensed with, and in such cases should make a special report?—Yes.

A discussion arose as to the special report, Mr. BIDDER contending that the report required by the Act to be made by the 1st of July was the special report; but it was pointed out to him by the Chairman that the report was described in the margin of the Act as the annual report.

Major MARINDIN remarked that he was not responsible for the dates, but he knew that there was a tremendous hurry through the whole thing to get it through in time.

Mr. BIDDER (to witness): I do not know whether you expressed your opinion as to the relative advantages of the continuous current or the alternating current?—I am not a scientific electrician. As to the details of it, I express in my report what the advantages of the two systems are.

You express in rather positive language what appear to be the disadvantages of the high pressure alternating system?—That is not mine, but Major Cardew's, my assessor. I quite agree with it.

Are you strongly in favour of the continuous system?—I think from the consumers' point of view there is no system which gives so good a supply as the direct current and storage batteries.

Is not that the continuous system?—The evidence before me was to the effect that over a large area the transformer system had great advantages, and I thought both were good. I should prefer not the continuous system quite as supplied by, I think, the St. James's and the Pall Mall, but as supplied by the Chelsea Company, where they supply entirely by the storage batteries. That is the one which I believe is the best.

None of the other districts are comparable in area with that of the London Company?—The acreage of the Metropolitan area and of the London area were not at one time very different; but the Metropolitan have since

Digitized by Google

dropped a large part, and so the area of the London is very much larger than that of any other.

Why are two years given to the London Company, whereas the Board of Trade insisted that the St. James's and Pall Mall should have one year?—I think there is a little difference in the two cases. The St. James's and the Pall Mall are in this position—that they are not called upon to supply anybody until after one year. Then you may be requisitioned, but you have no compulsory streets.

Why have the other company two years for the same thing?—The London Company are bound under two years to lay their mains over certain scheduled streets, and they are bound after 18 months to supply any other streets to requisition.

Why should not they come within the same obligations as the St. James's and Pall Mall do?—Eighteen months was thought fair all over London.

A discussion again arose as to the special report required by the Board of Trade.

On Mr. GRAY rising to speak on behalf of the Board,

Mr. LITTLER objected to anybody appearing for the Board of Trade, on the ground that they were neither in the position of promoters nor of opponents.

Mr. BIDDER also supported this contention, observing that no department of the Executive Government had any right to intervene between the petitioners and the parties to Bills before the Legislature.

The point having been argued, the room was cleared, and after spending some time in deliberation,

The CHAIRMAN announced that the Committee considered the point of so much importance that they would give their decision to-morrow.

The Committee then adjourned.

WEDNESDAY, AUG. 7.

On resuming this morning, the CHAIRMAN said that he understood that the application by the Board of Trade to appear by counsel had been withdrawn, and there was no necessity for the particular ruling.

Mr. GRAY said that the position of the Board of Trade was entirely neutral, and he was there merely to assist the Committee in any matter that might arise.

Major MARINDIN was then examined by the CHAIRMAN on his report on the Electric Lighting Orders. Asked as to the scope of the inquiry, Major Marindin replied that there were applications sent in from a large number of companies with different areas, and he had to determine more particularly what areas should be allotted to each company, and whether it was desirable that there should be more than one company in any particular area, and to decide generally as to whether it was desirable to adopt the system of districting altogether or to have competitive areas.

Was the inquiry a general one to consider the lighting of the metropolis generally, or only to consider the applications of certain companies?—It was in reference to the areas applied for by the different companies who sent in applications. It did not apply to any part of the parish outside of the area applied for. The Board of Trade wished to adopt a general scheme of electric lighting, and they wished to have guidance as to the best way of drafting the different orders, with the view of having them identical. I also inquired into the financial condition of the companies to a certain extent. The greater part of the inquiry was directed towards the advantages and disadvantages of the different systems, and a great deal of scientific evidence was given. I was quite satisfied that the whole of the systems which were advocated were practicable and worthy of a trial, without saying which exactly was the best system—in fact, I do not think anyone can say which is the best. None of the companies are tied to any system; they might adopt any system they pleased.

Did you consider that any of the systems proposed were dangerous?—Not with proper precautions.

Mr. POPE said with the exception of this Order no other Order would raise a preamble question at all. The sole question upon the subsequent Orders was with reference to the County Council requiring a clause about bridges which it was proposed to go over, and in this the Metropolitan Supply Company (for whom he appeared) had agreed with the County Council.

Mr. BATTEN said he wished to ask Major Marindin a very important question, viz., whether it was brought to his knowledge that the £100 Founders' Shares in the Westminster Company were to be £2,500 if this Order passed?

Mr. WALLACE: That is not so.

Major MARINDIN: There was nothing in the evidence about that. Evidence was given as to what the company was, and there was only a small sum subscribed.

Mr. BATTEN: Was it brought to your knowledge that the first founder who subscribed the first £500 was to have one-fourth of the entire profits of the sale of this undertaking if the Bill was sold to the adjoining company?

Mr. WALLACE: That is not so.

Mr. BATTEN (to Major Marindin): But at any rate the fact disclosed in the Memorandum of Association of the Westminster Company was not brought under your notice—that the founders were to have £2,500 for every £100 subscribed?—No.

Mr. HARRY WILKINS, the vestry clerk of St. James's, Westminster, was called, and stated that his vestry was in favour of limited competition at the present time between the direct and alternating systems. They originally opposed the London Company, but most of their objections to it had been removed, and they did not now object.

In cross-examination by Mr. MUIRHEAD, WITNESS said that they were waiting to see whether the direct or alternating current was the best, and until this was worked out by actual practice they preferred competing systems.

Asked if the St. James's would be able to supply all the wants of the parish in the event of the Provisional Orders not passing, WITNESS said that at present the St. James's had only got power over the southern portion of the parish.

Mr. PEMBER said that the Westminster Electrical Syndicate and the London Electric Supply Corporation had agreed not to oppose each other in the event of the former applying for a license.

Mr. BATTEN: That will answer our purpose.

The first witness called was Mr. BALFOUR, who, in answer to Mr. MUIRHEAD, said that he was Chairman of the St. James's and Pall Mall Electric Lighting Company. Witness was going into the detailed working of the Company, when

Mr. PEMBER said that he did not propose to ask any question as to the financial ability of the Company to do this work, but his learned friend wanted to make it a serious question as to this Company's mode of lighting.

Mr. MUIRHEAD then examined Mr. BALFOUR as to what he thought of a second company laying their mains alongside his Company's mains?—Witness said that it would be extremely difficult for them to do it, and it would be extremely inconvenient for people to have the streets up twice.

Mr. POPE: Perhaps you would like an absolute monopoly?

WITNESS: Well, we have got our license, and we are working satisfactorily. I think before an expensive competition were introduced it would be only fair to go on for another year or two, and then if we were found not to be working satisfactorily competition should be permitted. If competition is to go into a district like that it would be more difficult for the Companies competing to furnish the public at a moderate rate, because the amount of money they have to spend in laying duplicate mains is about double what one company alone would do. Besides that, there was the question of supplying energy to motors, and there it would be unreasonable, because we are the only people supplying energy. We say that our Company should have a fair chance of carrying on their work, and in the event of our not supplying the parish properly another company should be allowed to come in.

Mr. JAMES SWINBURN was next examined by Mr. BIDDER. Witness said that he was an electrical engineer with a large practical experience, and was acquainted with the system of the St. James's Lighting Company. It was a well-known system. The license was only obtained in 1888, and the works were in progress at the present time, and the best known means of supply would be at the command of everybody in that district. He thought it would be exceedingly hard for another company to come in at the present time. There was this distinction between the St. James's and the London—that the former was under a license for seven years, and if the latter got their Provisional Order it would be for 42 years, so that the two would be competing upon unequal terms. The larger the supply the cheaper they would be able to produce electricity. It depended very much upon the length of the mains. In the London Company's Order there were certain streets in which they were to be compelled to lay down mains specified in the second schedule to the Order, and these streets were the cream of the district.

With regard to the continuous-current and the alternating systems, which is the best?—I think it is very generally acknowledged by all electrical engineers that the alternating system is best for districts where the lighting is scattered; and the direct current is suitable in districts, like the St. James's, where all the lights are close together. With a low-tension current there was a considerable loss in carrying the current for a long distance, and that was diminished by the adoption of the high-tension alternating system, and it became almost in ignificant. With the alternating system they had to use more lamps. Storage batteries would be used here, and that meant extra safety against breakdowns. With the alternating system you have to depend upon duplicate machinery for security against breakdowns. Many of the streets were very narrow, and it was of importance that culverts should not be interfered with in digging.

LORD CRAWFORD said that they had a motor, what do you say to that?—There is nothing new in it, and no appreciable advance is known. American companies have wanted to use motors for a long time; and it is very important to the Westinghouse and Thomson-Houston systems, and they would have brought it into use if it had been practicable.

Cross-examined by Mr. PEMBER as to the evidence of Sir Wm. Thomson before Major Marindin, wherein Sir William stated that for large central lighting large engines were the best for reserve power, and for small domestic lighting in isolated cases storage batteries were very valuable, witness said that if he could only have one engine he would prefer the batteries.

Mr. BIDDER then addressed the Committee. He said that he would not ask them to throw out the Order, but to exclude that particular district of the St. James's from the district assigned to the London Company under the Order. The other parts of the Order he had nothing whatever to say to. The principle had been well recognised in the Act of 1888 and otherwise, that the giving to one company of a Provisional Order to supply particular districts was not to give them a monopoly, but that Parliament should consider whether it was reasonable that another company should come there. He submitted that it was not reasonable that the London Company should be allowed to come into the St. James's district. In the first place, in including St. James's district in the London Provisional Order the Board of Trade had not acted under the powers conferred upon them. They were expressly forbidden from granting an Order in the district of any local authority without the consent of that local authority, unless they made a special report stating the ground upon which they had dispensed with such a thing.

The CHAIRMAN: Does the learned counsel seriously contend that this special report is necessary?

Mr. BIDDER: Certainly.

The room having been cleared, the Committee deliberated, and

Digitized by Google

The CHAIRMAN said that the time had elapsed for considering whether a special report was necessary or not, and it ought to have been raised at an earlier period.

Mr. BIDDER quoted Major Marindin's report to show that the inclusion of the St. James's district in the Order of which his company complained was really a consideration given to the London Company for requiring them to remove their existing overhead wires. The removal of overhead wires might be a very desirable thing, but he protested against the London Company being introduced into the St. James's district in order to have them removed. Another reason for excluding the London Company from St. James's was that they were getting nearly half of the whole of the Metropolis, or a population of something like two millions. The district was far larger than the existing capital of the London could carry on the works with, and something like double the capital would be required to supply the whole of their districts. Their lordships would be doing less injury to the London in saying that they should not go into the St. James's district, seeing that they had got a much larger district already than would employ the whole of their capital. In the course of three or four years circumstances might arise by which the local authority would think it desirable to give its consent to a second company to come to Parliament to supply the St. James's district. He therefore asked the Committee to strike St. James's out of the present Order.

Mr. PEMBER, in reply, said that the London Company had taken all kinds of districts, good, bad and indifferent, whereas the St James's Company had selected this specially good part of the Metropolis only. The capital of the London Company was £1,250,000, of which over £800,000 had been already subscribed, and £500,000 spent. It was only when these companies were conducted on a large scale that they could be remuuerative. Then Mr. Bidder had told them that the London Company had been allotted nearly half the Metropolis ; but that was not accurate. There was not a single parish on the north of the Thames, except Clerkenwell, where they were not in competition with other companies ; and on the south of the Thames they had a vast deal which was not remunerative, as in Bermondsey and Rotherhithe where no other company would go. As to the consent of the vestry not having been given, they had had the clerk of the vestry (Mr. Wilkins) who was deputed to say that the vestry did consent. These large companies must have large areas, and the good part of their area must be taken to pay for the bad. Major Marindin had decided that competition was a wise thing, and that it should be a competition between alternating currents and direct currents. Then both systems would be on their trial. People would have a chance of taking their supply from the one or the other, and by that means they would have the most advantageous competition, and the different systems would have full scope.

The room was cleared for the Committee to deliberate. On the public being re-admitted,

The CHAIRMAN said : The Committee will proceed to the consideration of clauses so far as the London Order is concerned.

Mr. BIDDER : Does that mean that you have decided against me ?

The CHAIRMAN : Certainly. We will now proceed with the London clauses, as we understand that those clauses will govern the other Orders.

The clauses of the London Company were then discussed.

Mr. FREEMAN (on behalf of the County Council) then brought up a new clause as to bridges of the London County Council, which after considerable discussion was adopted as follows :—

"Whereas Westminster Bridge is the only bridge across the River Thames within the area of supply, therefore, for the purpose of laying a main or mains across the said bridge and the approaches thereto, so far as they are vested in the County Council, the Undertakers may exercise the following powers, and shall be subject to the following conditions :—(1). The Undertakers shall be entitled to use for laying such main or mains a space either under the carriage-way or the foot-way of the said bridge and approaches, or partly under the carriage-way and partly under the foot-way, not exceeding in sectional area the area contained within the dimensions of sixteen inches wide and eight inches deep in such position as the Council may prescribe. (2). If the Council find that a space of sixteen inches wide by eight inches deep cannot be used for this purpose without undue interference with the fabric of the bridge or the carriage-way or foot-way thereof, then the Undertakers shall be entitled to use a space or spaces sufficient in aggregate sectional area to admit eight mains each of dimensions (including any cover) of not exceeding four inches square, such mains being placed either together or separate in such position as the Council may prescribe. (3). If the Undertakers require any greater space than that hereinbefore specified, nothing herein contained shall prevent the Council from authorising by consent in writing the use of such greater space as can be afforded without undue interference with the said fabric carriage-way or foot-way. (4). The Undertakers shall not break up or interfere with any part of the said bridge or the approaches thereto, or the road-way or foot-way over the same except in accordance with plans, sections, and particulars previously submitted to and approved in writing by the said Council or as may be settled by arbitration as hereinafter provided. (5). If within 28 days after the submission of such plans, sections, and particulars to the said Council, with notice in writing requiring them to approve the same, the said Council shall disapprove or fail to approve such plans, sections, and particulars, then such plans, sections, and particulars shall be referred to an arbitrator to be appointed by the Board of Trade on the application of either the said Council or the Undertakers. (6). Such arbitrator shall consider and determine, having regard to the structure and design of the bridge, and to the provisions of this section and all other circumstances of the case, on what terms and conditions and in accordance with what plans, sections and particulars such main or mains shall be laid across the said bridge and approaches subject to the provisions of this section ; and the Undertakers shall be bound to comply with and observe all the terms and conditions imposed, and the plans, sections and particulars approved by such arbitrator. (7). The Undertakers may, if so required in writing by the County Council (instead of breaking up or interfering with the said bridge or any part thereof), place their main or mains wholly or in part along and on the outside of the said bridge in such position and with such covering as may be prescribed by the County Council."

After some verbal amendments the Order was passed.

Mr. SAUNDERS, Q.C., briefly opened the Westminster Electric Supply Corporation Order, and the Committee adjourned.

THURSDAY, AUGUST 8TH, 1889.

The Committee, after hearing evidence, confirmed the Order granted by the Board of Trade to the Westminster Electric Supply Corporation. The Order was unsuccessfully opposed by the City of Westminster Electrical Syndicate, and their application for a clause preventing the Corporation from opposing them on grounds of competition if they applied for a License or Provisional Order was refused. Westminster, Lambeth, Vauxhall and Chelsea Bridges were, by arrangement with the County Council, excluded from the area of supply.

[*A full report of Thursday's proceedings will appear in our next issue.*]

THE VESTRY OF ST. JAMES, WESTMINSTER, AND THE ELECTRIC LIGHTING ORDERS.

The Vestry of St. James has directed their Clerk to address a letter to the Board of Trade, of which the following extract covers the most important clauses :—

"I am in the first place to remind the Board that in the metropolis the vestries and District Boards of Works are the Local Authorities, except as regards streets which were lighted by the Metropolitan Board of Works, and that it is to these last-mentioned streets alone the jurisdiction of the London County Council, as successors in law to the Metropolitan Board of Works, appears to extend under the Electric Lighting Acts.

Both the Model Form of Order issued by the Board, and the filled up Order, were submitted to the Vestry at so late a period of the Session as to preclude careful consideration in detail. I am, however, to point out that the 13th clause of the London Company's Order, taken in conjunction with the interpretation of the expression "County Council" in Clause 2, would appear to give the Council concurrent jurisdiction with the Vestry over the breaking up of streets which are vested solely in the latter. The Vestry are of opinion that the duties of the County Council under this clause should have been clearly limited to streets, bridges, &c., under their control, and to cases where any proposed works were likely to interfere with any sewer, or other work, vested in the Council.

The 12th Clause of the Order confers upon the Council powers with regard to overhead wires, which, by the principal Act, are expressly reserved to the local authorities ; and as the Order is made subject in all respects to the principal Act, it would seem that the Council and the local authority will, in this particular also, have concurrent jurisdiction under the Order. I need scarcely point out that the possession of concurrent jurisdiction involves the possibility of conflict between a central and local authority, which may be followed by very regretable results.

I am further to submit that, in view of the expressed intention of the Government to transfer to the Council powers under the Electric Lighting Acts now vested in the Board of Trade, it is highly undesirable that the Council should also be vested with powers at present exercised by the Local Authorities under statute. If the Council were constituted the Local Authority as well as the controlling department, they would be placed in the illogical position of being an appellate tribunal against their own decisions, and in some cases would be called upon to appoint an arbitrator to decide between themselves and the Undertakers, a proceeding calculated to deprive the award of the arbitrator of much of its value.

The Vestry regret that further time was not allowed them for considering the new provisions embodied in the Model and in the filled up Order, before the latter was submitted to Parliament for confirmation, and this regret is deepened by a feeling that it is futile to ask Parliament, at so late a period of the Session, to virtually recast the Order in some material respects. The Vestry trust, however, that the considerations which they now venture to urge may receive due weight when the Board are next called upon to frame an Order relating to the metropolis."

Telephone for the Madras Harbour Works. — The local Government indented some time ago for a telephone apparatus for the Madras Harbour Works, but were informed by the Home Government that they had not complied with the indent as an air speaking-tube was considered better by the Admiralty. The local Government, however, ventured the differ with the Admiralty, and insisted on having a telephone for the divers, as the air tube had often been tried on the works and found useless, on account of the waves, extra piping and continual knocking together of the several tubes, which rendered it impossible to hear anything, besides having to stop the pumps.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

"THE ELECTRICAL WORLD" OF NEW YORK.

Arrangements have been made by which "THE ELECTRICAL WORLD" OF NEW YORK *can be obtained from* "THE ELECTRICIAN" *Office, 1, Salisbury-court, Fleet-street, London, E.C.*

The Rate of Subscription (payable in advance), is **£1 1s. 0d.** *per annum.*

Subscriptions are received by this Company for all Continental and American Electrical Journals. Subscription Rates on application to "THE PUBLISHER." *Remittance must accompany order* IN ALL CASES.

LIGHTNING CONDUCTORS.

The *Journal* of the Institution of Electrical Engineers containing the report of the discussion on Dr. LODGE'S Paper on Lightning is now in the hands of the members, and it may therefore not be out of place to review the subject here. Dr. LODGE'S communicated reply will be found in another column. We are a little apt to look upon the whole as a very interesting and perhaps somewhat amusing discussion between the disciples of the old lightning-conductor theories and the more modern; but it must be borne in mind that it is not a question of merely theoretical importance, or of passing interest, but one on which hangs, at any moment, lives of fellow creatures and the safety of enormous property. The earlier investigators either omitted self-induction from their calculations altogether or absurdly underestimated its importance. Within the last few years the study of self-induction in all branches of electric science and practice has been eagerly followed, and the various methods of measuring it became at one time quite a fashionable, though, perhaps, rather useless hobby. Dr. LODGE tackles the question fully armed with all the most recent knowledge relative to Leyden jar discharges, thereby being enabled to see farther than the great men of old. As he frankly says, anyone else *might* have done the same thing; but the difference between Dr. LODGE and other people is that he did and other people did not. No one reasonably conversant with the science can deny that the discharge of a Leyden jar through a comparatively small resistance is oscillatory. Obviously, if there were no dissipation of energy by resistance (and by radiation) the oscillations would go on for ever; if the resistance is increased till the energy lost on it in discharge is equal to the whole energy of the charge there will be no oscillations. We do not quite follow Dr. LODGE'S calculations as to the self-induction of his air condenser. The self-induction of a conductor whose ends are not

Digitized by Google

coincident is an unthinkable sort of thing. One, therefore, naturally thinks of the return current, which is, in this case, the electrical displacement between the plates. If this is assumed normal to the surface of two discs, the self-induction comes out the same order of figure as Dr. LODGE's, except when the condenser-plates are exceedingly close together; in fact, it does not much matter where the return displacement is assumed if the conductor carrying the discharge itself is comparatively small. Dr. LODGE assumes that it is exceedingly small, even in the case of a lightning flash. The electric resistance of a wire of blue hot air, one millimetre in diameter, is probably exceedingly small. Air in the inside of incandescent lamps conducts pretty freely as soon as the carbon gets to a white heat, and the heating due to a lightning flash would rarefy the air in its path, and heat it to such a temperature that its resistance might be surprisingly small. The mutual induction of the parts of the stream would make the current flow on the outside of the hot air wire; in fact we might speculate as to whether a lightning flash is not conveyed by a tube of conducting air. This would, on the other hand, increase the resistance of the air-wire. In fact, the resistance would depend on the vibration frequency, which complicates the problem considerably.

The full appreciation of the effects of self-induction is not the only novelty in Dr. LODGE's treatment of the subject; he draws a clear distinction between prepared and sudden impulsive rush discharges. We believe this is new. Of course there was the old striking by induction. This was not very clearly defined. In 1871 or 1872, Prof. PERRY, lecturing on lightning at Clifton College, killed a mouse who was waiting for some subsequent experiments upon him. The mouse was supposed to have been killed by the sudden dissipation of the charge induced on his back by a conductor connected with a Leyden jar with which the learned professor was experimenting, and this is, we think, what was known as killing by induction—at least so we remember Prof. PERRY's interpretation. Is it not, however, more likely that death ensued owing to an oscillatory discharge surging to and fro and spitting off from some neighbouring conductor?

We do not think Dr. LODGE very clearly explained what he meant by the path being prepared or unprepared in the two cases. It is not very clear why an unprepared path should not prepare itself instantly so as not to differ in effect from a prepared path. If the path consists partly of dielectric and partly of conductor, in the prepared case we can imagine that the point of the conductor would be charged and the whole stress would be supported by the dielectric up to the instant of the flash. In the sudden rush case, self-induction might prevent the instantaneous charging, so that the flash would take the path in which the initial insulation per centimetre could be broken down most easily. But this is somewhat vague.

It is strange that, though during the discussion many people objected to a tin plate being taken as representing a cloud, no one found fault with the relative proportions of dielectric and metallic conductors in the circuit. A Leyden jar, or a tin cloud discharging through a few inches of air, is not the same as when discharging through the air with a foot or many feet of metallic conductor in series. In most of the experiments this is not to the point, but we cannot help wondering whether Dr. LODGE has not forgotten the relative lengths in the case of lightning. Given a lightning flash. A certain amount of energy is to be dissipated with as little danger to life and property as possible. If resistance is inserted to damp the oscillations, and that resistance is confined to a very small fraction of the length of the spark, surely in the first place the expenditure of energy is concentrated where it is not wanted, and a difference of potential is produced between the ends of the conductor, due to resistance, which in conjunction with the self-induction effect may tempt the lightning to break down another path for itself. Of course, once the lightning has broken down the insulation of its path through the air, the resistance of that path is so low that it may not care to leave it.

It may, perhaps, be worth while to remark that the oscillatory discharge must not be confused with the multiple flashes visible to the eye in the case of lightning. It is even difficult to see how the oscillatory discharge, whose period may be comparable to one-millionth of a second, could be made visible by a revolving mirror, as the conducting air would remain practically equally incandescent all the time. If the oscillations are visible in a mirror this might prove that the light of a flash is not due to the incandescence of the air. The repetition of lightning flashes may be observed by borrowing a watch and removing the balance wheel, and then counting the apparent number of seconds hands made visible by the light of the lightning flash while the wheels are whizzing round. This may show that cloud is a bad conductor. If a flash discharges a small surface of cloud, leaving the rest charged, the charge would take some time to equalise itself. The discharged part would charge up; but long before it got to its old point it would discharge again, as there would be a path of comparatively hot air ready for it to break open. It would seem highly probable that if the cloud is a bad conductor—in fact, its badness is obviously a matter of degree—an oscillatory flash must itself take down a greater charge than a single one. The patch of cloud first discharges, and over discharges. This makes the charge of the rest of the cloud rush in to fill the vacancy. The charge, less the part lost due to resistance and radiation, comes back, but does not force the newly-arrived or usurping charge back with the same force as the negative charge urged it in, so that on second discharge, or rather second oscillation, there is a greater discharge than if the patch of cloud had been insulated from the rest.

The result of the discussion is roughly that we do not know anything to speak of about lightning conductors. This is really infinitely better than being saturated with absurdly erroneous ideas. In the meantime we do not quite know how to be secure. We notice that Dr. LODGE has patented a lightning conductor which is to prove our salvation, and we earnestly hope it will soon be in the market.

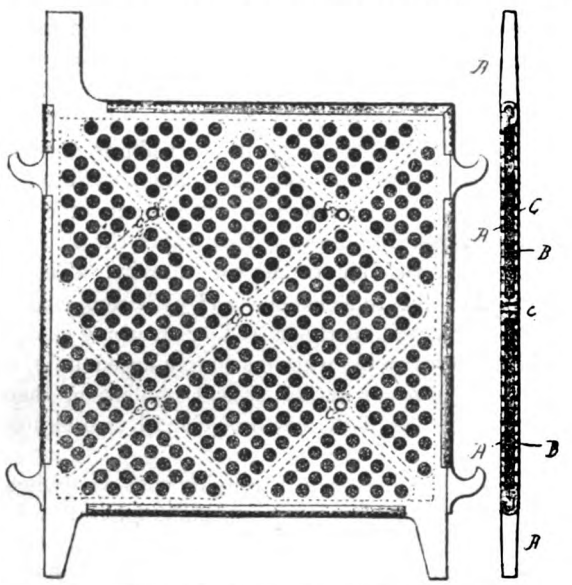
REVIEWS.

The Mutual Electric Manufacturing Company.

We have received from the Mutual Electric Manufacturing Company of Brooklyn, N.Y., an elaborate circular of some 30 pages, giving in a popular form an account of the particular system worked by them. This publication—which we may remark *en passant* bears a great similarity both externally and internally to the magnificent catalogue issued some months ago by the Westinghouse Company, and alluded to in *The Electrician* of December 7th and 14th, 1888—would be much improved if the fine cuts which illustrate it were placed opposite the matter referring to them instead of being, as at present, arranged in a somewhat haphazard fashion. The patents owned by the Mutual Company are those of their chief electrician, Mr. E. R. Knowles, and embrace amongst other things a dynamo, an arc lamp, an automatic regulator, a meter, and a storage battery. The system of distribution devised by Mr. Knowles merely consists in supplying from one set of dynamos and by the same conductor both arc and incandescent lamps. This is effected by means of storage batteries arranged in sub-stations, and charged during the daytime with a constant current of 15 amperes. When the arc lights are required the batteries are cut out. Each lamp and

Digitized by Google

set of batteries is furnished with an automatic polarised cut-out, those on the arc lamps operating when the current is in one direction and those on the batteries operating when the current is reversed. The Knowles' automatic current-regulator is of two types, one shifting the brushes on the dynamo commutator and the other switching resistances in or out of circuit. In both types the regulator consists of a nest of gear-wheels, which are revolved in one direction or the other by the action of an armature suspended between two electro-magnets, one of which is energised when the current exceeds the normal, and the other when the current falls below it. In the Knowles' meter, which is of the clockwork type, the movements of the core of a solenoid under the influence of the current actuate a pointer. The end of this pointer is in close proximity to a drum, which is revolved at stated intervals by clockwork. On the drum are arranged a number of longitudinal ribs or teeth of different lengths; consequently when it revolves, more or less teeth come into contact with the pointer, according as the latter is nearer one end or the other of the drum. Whenever the pointer makes contact with one of the teeth on the rotating drum it closes the circuit of an electro-magnet actuating a set of dials on which the ampere-hours are finally recorded. The plates of the Knowles' storage battery (*see* figure) which, accord-



The Knowles Storage Cell Plate.

ing to the catalogue, "will *never buckle* or twist under proper handling," which never sulphate, and whose active material will not fall out, consist of two halves, A A and B B, bound together by rivets at the points C C, and between which the active material is placed in the form of a sheet, the enclosing plates being perforated to give the electrolyte access to the active material. The plates are cast of an inoxidisable alloy, which is said to contain no mercury. The Knowles' system, it will thus be seen, contains several novel features, and although we are unable to endorse all the superlatives in the catalogue, there can be but little doubt as to the ingenuity displayed by the chief electrician to the Mutual Electric Manufacturing Company.

Applications Industrielles des résidus provenant des Piles aux Bichromates. By G. Fournier. (Paris: Bernard Zignol, 1889.)

The utilisation or reconversion of the residual products of the bichromate cell was for a long time reckoned amongst the chief desiderata of electricians, and many were the attempts to solve the problem. Even to-day, notwithstanding the enormously increased facilities for obtaining electrical energy, we must still admit that the question maintains a certain importance, and we therefore welcome this little brochure of M. Fournier as affording the opportunity of reviewing the last word which chemical science has had to say upon the subject. The author is contented to point out by what processes certain saleable materials may be obtained, and he necessarily leaves the question of commercial availability for local consideration, when the cost of collection, manipulation, &c., can be taken into account.

M. Fournier's method of operation does not seek the regeneration of the solution, but, as we have intimated, the extraction of saleable products. These are "chrome alum," potassic or sodic sulphate, chromate of zinc, and chromic acid.

The spent liquid from the cells will contain the sulphates of potassium (or sodium), of chromium, and of zinc, together with chromic and sulphuric acids. The first operation is to add granulated zinc until the acid has been neutralised. This done, if the *potassic* bichromate has been employed, we shall find a deposit of crystals of "chrome alum" (the double sulphate of chromium and sodium), which salt has a market value as a mordant for use in dye-works. If the soda salt is used we do not get this deposit, the double sulphate of soda and chromium being highly soluble.

The next operation is to extract the chromic oxide. For this purpose more zinc is added, and the solution is heated to 100° C. The chromium is precipitated in the form of oxide, and the solution contains only the sulphates of zinc and of potassium or sodium, as the case may be. To this solution is added "milk of lime," which precipitates the zinc oxide, and the remaining potassic or sodic sulphate may be drawn off, and after evaporation is ready for sale.

The mixed precipitate of sulphate of lime and oxide of zinc is next freed from excess of lime by the gradual addition of a solution of zinc sulphate. To the liquid thus obtained a solution of bichromate of potassium is added, producing a precipitate of yellow zinc chromate, for which a ready market may be found. The liquid remaining contains only potassic sulphate, and is of course added to the solution previously obtained.

We return now to the chromic oxide, which readily yields dye materials of some value. By calcination we obtain a fine shade of green, and various shades of the same colour are obtained by combination with boric, picric, and some other acids. Or by dissolving in dilute sulphuric acid we obtain a valuable mordant. Lastly, we can prepare chromic acid by calcining the oxide with a mixture of carbonate of lime and quicklime, and treating the product with dilute sulphuric acid. The process, however, requires to be carried out with special precautions which we have not space to enumerate.

It will be understood that we have not attempted to more than briefly indicate the general character of the operations proposed by M. Fournier, and to those who are especially interested in the chemistry of the bichromate cell, and still more to any who, not being competent chemists, may feel tempted to try the experiments described, we strongly recommend a perusal of the original work. We must add, in conclusion, that some alternative methods of treatment are given which we have left wholly unmentioned.

Practical Electric Bell Fitting. By F. C. Allsop. (E. and F. Spon. London, 1889.)

The present volume, which is a reprint of some articles which originally appeared in the columns of the *English Mechanic*, is the third or fourth publication dealing with electric bell fittings that has come under our notice during the last few months. It is a good practical treatise upon a subject which demands only the most elementary knowledge either of electricity or mechanics. The volume consists of some 140 pages, and is adorned with nearly 150 illustrations; it is written in simple, straightforward language, and will doubtless prove of the greatest service to the class for whom it is intended.

BOOKS, &c., RECEIVED.

THE BIRMINGHAM EXHIBITION.

From a technical point of view the Birmingham Electrical Exhibition is likely to be memorable for the excellence and the representative character of the display by well-known firms of their well-known manufactures, rather than for the number or the importance of the novelties displayed. That it will prove a great attraction to the public is unquestionable, and that it will also repay a visit from the members of the profession cannot be gainsaid; but, so far as is at present discoverable, there will not be many important exhibits with which our readers have not already had an opportunity of becoming more or less acquainted. Such being the case we may pass by some features of the show which will loom most largely in the public gaze with comparatively brief mention, and reserve our space chiefly for detailed descriptions of appliances which are not at present so familiar to the electrical world. In this preliminary article we content ourselves with little more than a general survey of the leading features.

Considering that Bingley Hall was only placed at the disposal of the Executive Committee a fortnight before the day fixed for the opening ceremony, the state of preparedness which the Exhibition now presents is on the whole very creditable to the responsible officials. It is, however, somewhat unfortunate that with the exception of the lighting, which is nearly complete, the electrical exhibits are in most instances in a backward state; and it is this, doubtless, which gives the impression that the industrial portion of the Exhibition to some extent overshadows the electrical. The Machinery Hall and heavy electrical exhibits will, however, be complete in the course of the next few days, when the electrical character of the Exhibition will no doubt reveal itself more prominently. Meanwhile the space allotted to some of the most important firms is still vacant, and the stands of many others are as yet incomplete.

The arc lighting is throughout excellent and ample, and the incandescent lighting, although at present of somewhat modest dimensions, is very satisfactory. The Anglo-American Brush Corporation light a bay of the main building with eight 2,000 candle-power Brush arcs. These lamps are run in parallel off a Mordey transformer at 100 volts, each lamp having an impedance coil in series with it. The current is supplied by a 2,000-volt Mordey alternator, rope driven by a Brush vertical compound engine. This machine (Fig. 1) is one of the same size as those which were recently run in parallel, and as alternate-current motors, in the works of the Corporation. The normal speed of the machine is 650 revolutions, and the output 37,500 watts, or 50 electrical horse-power as generator, or 50 horse-power as alternate-current motor. The excitation of this machine is comparatively small; 500 watts are required for this purpose at full load, and rather less with lighter loads. One point worthy of notice in this dynamo is the very small waste of power that takes place when the machine is run on open circuit or with a small output. When excited to give the full electromotive force at the full speed, but with no external load, it requires only 3 horse-power. This is an important point, as it is sometimes necessary to run alternators for a considerable portion of the day with a very small load indeed, and it is therefore desirable that when so running the absorption of power should be as small as possible. The commercial efficiency of the machine with full load is fully 90 per cent. There are some differences in details when compared with the first machine of this type which we described in our columns about a year ago (*The Electrician*, May 25, 1888, p. 81), the modifications being such as to add to the mechanical stability of the machine. The copper sheath which was previously used to cover the revolving magnet for the prevention of disturbance of the air, has been replaced by an iron sheath cast in one with the magnet itself. The exciter is of the ordinary type Victoria machine, and for convenience is mounted directly on the shaft. The exciter shown in the figure is a larger one than is required for exciting the alternator, being, in fact capable of exciting two such machines. The same alternator also supplies current to another 24-kilowatt Mordey alternator running as a motor, which in turn drives an E_2 "Victoria" dynamo, supplying three 5-ampere arcs and a number of incandescents. The lighting undertaken by Messrs. Fowler, Lancaster and Co., who employ Thomson-Houston plant, will comprise when completed forty 2,000 arcs—twenty-four in the main building, six in the winter garden, and ten in the streets outside the Exhibition. These lamps are run off two 35-light dynamos, belt driven off an 80 horse-power Armington and Sims engine. Mr. A. A. Goldston, of Middlesborough, lights the Machinery Hall with five remarkably steady 2,000 candle-power Brush lamps; he also has eight lamps in the main building, and two in the boiler-room. These lamps are run off a 25-light Brush machine, belt driven by a 10 horse power nominal high-speed Robey engine. This circuit is run indifferently either with the ordinary Brush regulator or with an electric governor on the engine. In series with these 15 arcs are fifty 32 candle-power incandescents of the Bernstein pattern, fitted with an automatic short-circuiting device (Fig. 2) brought out by Mr. Goldston. Two strips of platinum, T T (Fig. 3), are fastened to the leading-in wires W W, and fit loosely on to the china wedge V, which is suspended by the spring S. Fastened to the base of the wedge is another strip of platinum, P P (Fig. 4), the leading wires, W W, running freely through large slots at the extremities of this strip. On the filament breaking the two

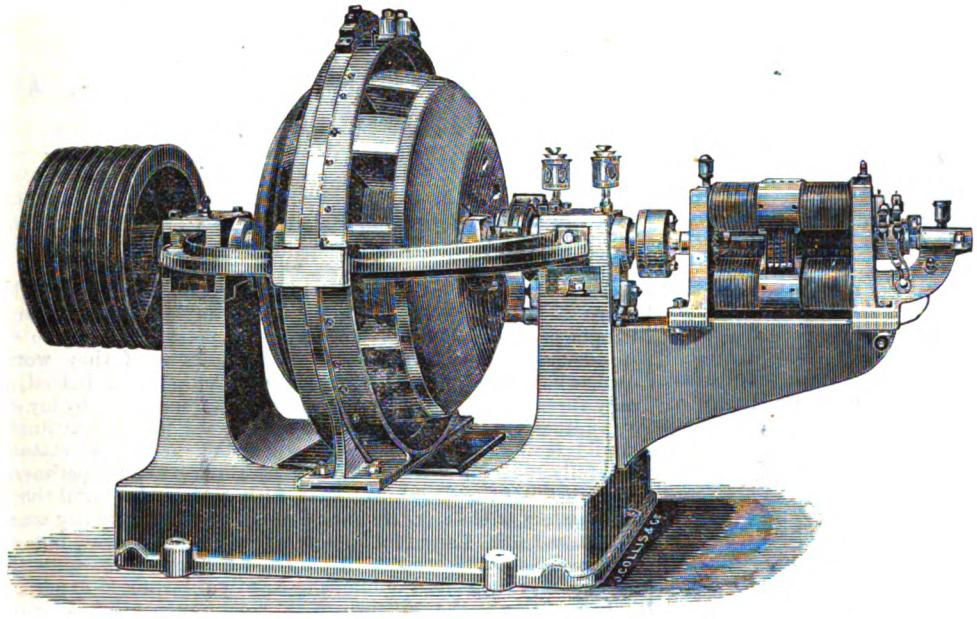

Fig. 1.—Fifty Horse-power Mordey Alternator.

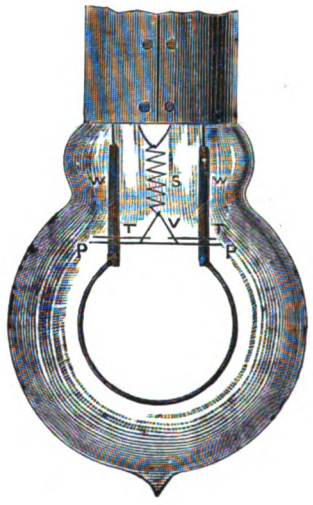

Fig. 2.

Digitized by Google

halves fly apart, and the separation of T T allows the spring to lift the wedge, bringing P P into contact with the two upper strips; the break is thus bridged, and the continuity of the lamp circuit is maintained. The Planet Electrical Engineering Company will run eight 2,000 candle-power Alpha arc lamps, placed in the main building. This circuit will be supplied by an Elwell-Parker dynamo, driven off the main shafting. Scott, Ernest and Co., of Newcastle-on-Tyne, light a bay of the main building with six of their new 2,000 candle-power "Tyne" arcs. These lamps, which are of the rack and pinion type, are arranged in parallel, and the current is obtained from a "Tyne" shunt-wound four-pole machine, with disc armature and deeply embracing pole-pieces. This machine, which is driven by a high-speed Robey engine, gives 65 volts at 850 revolutions. The refreshment stalls are lighted by Elwell-Parker, the lamps being run off a battery of accumulators charged from an Elwell-Parker machine, situated on a stand of Messrs. Crossley Brothers, and driven by one of their gas engines. This stand is profusely lighted by some fifty 16 candle-power incandescents, also run off an Elwell-Parker machine driven by an "Otto." The main shafting of the Machinery Hall, from which will be driven the dynamos supplying current to the various power circuits, is driven by a 30 horse-power compound Robey engine and an 80 horse-power compound engine by Messrs. Ruston and Proctor. Steam is supplied to all the enginess from two 300 horse-power Galloway boilers working at 100lb. pressure. The Machinery Hall is large enough to provide ample room for the engines and dynamos which it is proposed to put in it. A broad gallery runs across the middle of the hall about 15ft. above the floor, from which visitors can obtain a good view of the machinery.

Fig. 3.

Fig. 4.

A novelty in electrical fittings is shown by Messrs. Thonet Bros., of Oxford-street, in the shape of a bent-wood electrolier. The General Apparatus Company have a handsome case filled with their well-known artistic fittings, shades, electro-medical apparatus, switches, &c. Mr. Julius Sax shows a large assortment of burglar alarms, electric tell-tales, electric water-gauges, and similar apparatus. The Admiralty send an interesting exhibit, comprising several Whitehead torpedoes, Wheatstone's firing keys, and other submarine mining instruments. Nalder Brothers and Co., of Horseferry-road, Westminster, have a very creditable exhibit of electrical and electrical engineering instruments. Among these we noticed the ammeters and voltmeters brought out by the firm, which combine good strong work with high finish. The former have a very nearly even scale from beginning to end, while in the voltmeters the last half of the reading occupies nearly four-fifths of the whole scale. There is also an arc lighting ammeter with a similar scale, *i.e.*, with the readings near the normal current as much spread out as possible. The latest pattern of Profs. Ayrton and Perry's secohmmeter * is also shown, and the "secohm" standards are expected very shortly. The firm also show their form of D'Arsonval galvanometer and the usual standard patterns of resistance coils, bridges, and reflecting galvanometers, the latter having a convenient arrangement of the coils which makes the needle system very accessible. The whole exhibit is noticeable for the first-rate workmanship and finish for which this firm has acquired a high reputation. Henley's Telegraph Works Company, Walter T. Glover and Co., and John Fowler and Co. show a varied assortment of electric light and telephone cables, the last-named firm making a fine display with Tatham lead-covered cables. Lacombe and Co., of Westminster, who are supplying all the carbons for the lighting of the Exhibition, exhibit battery, telephone and electric light carbons, the latter ranging from the tiny pencil of the laboratory lamp to the huge fluted rods for lighthouse and search-light work. Conradty, of Nuremberg, also shows a large variety of arc light and telephone carbons. The Electrical Power Storage Company have a striking exhibit, comprising the different types of their storage cell, and a regulating switchboard fitted with their steelyard ammeter. Buller, Jobson and Co. exhibit, amongst other things, a large standard of wrought-iron poles and channel arms, which is fitted with over 400 varieties of insulators. A neat and workmanlike display is made by Mr. T. Coad, of Soho-square, who shows a number of portable electric lamps for miners. The Edison-Swan Company have a large case containing incandescent lamps of every candle-power and variety of bulb. Mr. J. C. Lord, of Birmingham, shows a very compact arrangement, consisting of a Waverley turbine and a 5-unit shunt-wound Elwell-Parker dynamo, coupled direct on the same bed-plate. The turbine runs at 1,100 revolutions and is capable of working up to 22 horse-power.

The heavy electrical engineering exhibits, as we have remarked above, are not at present in a very forward state, but they will, when ready, be of an interesting description. Messrs. Laing, Wharton and Down will exhibit the Thomson welding apparatus; the United Electrical Engineering Company will have in operation a telpher line; and the display of motors and electric light engines promises to be varied and excellent. The National Telephone Company, it should be mentioned, are very much to the fore with a most artistically-got-up call office, which has been specially opened for the convenience of visitors to the Exhibition.

* See *Electrician*, June 28, p. 193.

LIGHTNING, LIGHTNING CONDUCTORS, AND LIGHTNING PROTECTORS *

The following is the reply to the discussion on "Lightning, Lightning Conductors, and Lightning Protectors," communicated by Dr. Lodge to the *Journal* of the Institution :—

To a person unaccustomed to controversy, like myself, I find there is an absurd tendency to accept any position which may happen to be suggested as appropriate to me, and to reply to objections raised against a number of shady views as if they were my own, when they are really not mine at all; being, indeed, often only supposed to be mine because they are repudiated by my critic.

Another tendency, more strenuously to be guarded against, is a stupid feeling of semi-irritation when one finds that statements carefully recorded as the result of much thinking and experimenting, combined with some acquaintance with the fundamental theory of the masters of the science, are called dogmatic and lightly set aside, not on account of any real objection or valid argument, but solely and conspicuously because they do not happen to fit in with the speaker's preconceived opinions or hastily interpreted experience.

In replying to the criticisms with which my paper has been thus far honoured, I shall endeavour to resist both these tendencies; and especially shall I try to pick out of the criticisms those points which seem to me wholesome and salutary, and which I can more or less completely accept.

First of all, I must clear away some misapprehensions which have arisen in connection with questions of history and priority. They have arisen partly through misapprehension of what I said or intended to say, partly on account of a distinct oversight on my part in not acknowledging some prior work of Professor Hughes and M. Guillemin in the same direction.

To take the last first. I well knew that experiments in connection with lightning protectors had been made by M. Guillemin and Professor Hughes, because after my Society of Arts lectures Professor Hughes was good enough to write me an account of these experiments, and to consent to my request that his letters should be published in *The Electrician*. There they are for all to see, and it was a mere oversight that I did not refer to them in the corresponding portion of my paper. I suppose it was because I was trying to explain the *facts* quickly, and was not thinking about history or priority. I can assure Professor Hughes that nothing was further from my intention than to claim, or by silence to suggest a claim to, any priority in connection with such experiments.

These experiments showed clearly, in 1865, that no simple shunt arrangement could entirely protect a telegraph instrument from a Leyden jar discharge; and though they hesitated to press their conclusion to the case of lightning in all its completeness, yet I venture to think their experiments demonstrated this also. Demonstrated—not, of course, that lightning protectors can never protect,

* From the *Journal* of the Institution of Electrical Engineers.

Digitized by Google

nor that they may not always *partially* protect, but that in a number of cases they may partially, yet very seriously, fail.

That is one point where I hope I have now set myself right; the other is due, not to an oversight of mine, but to a misapprehension by my critics of what I intended to say. In emphasising the importance of the "impulsive rush" case of lightning discharge (the only one very liable to occur, perhaps, during a heavy shower) with reference to the absence of protective virtue from points, and the ease with which they, as well as everything else, could be struck by a noisy and destructive flash, I said: "The steady strain case was the only one ever contemplated by the older electricians; in fact, so far as I know, it was my experiments last year which first called attention to the other case."

These words I used, and these words I still repeat. But the reason I use them was not, I need hardly say, to claim a miserable figment of priority in so trivial a matter, but to emphasise the fact—for I believe it to be a fact—that the impulsive rush case of lightning discharge had not previously been attended to, and that hence many vitally important features had been overlooked.

In the "steady strain" case, points fizz off quietly and are not easily struck by a flash. In the impulsive rush case (*pace* Mr. Wimshurst for the present) they do nothing of the kind.

The important thing, therefore, in the words I have quoted is not the words "my experiments," but the words "experiments last year." It is not to claim the authorship, but to emphasise the recentness of the observations of this hasty and unprepared-for discharge.

It may be that the calling attention to the possibility of this case of lightning discharge is after all not recent—I only said it was recent "*so far as I know;*" but, if noticed before, it has not been emphasised or even mentioned in any books or papers on the subject that I have seen. Nor, indeed, do any of my critics really assert that it is an old idea.

Professor Hughes seems to think that I mean, by "the impulsive rush," a Leyden jar discharge in general, and refers me back to the year 1752, when a Prof. Muschenbroeck, or his pupil Cuneus (*vide* Ganot or Deschanel *passim*), appears to have anticipated me by something over a century. But the gentleman who first noticed an electric spark—Dr. Gilbert, I presume—must be credited with a still earlier knowledge of an "impulsive rush" in that sense. That, however, is hardly the sense I intended.

Mr. Wimshurst, in his remarks at the first evening of the discussion, seemed to think I meant to claim the mode of obtaining impulsive rushes from the outside coatings of two Leyden jars; and pointed out that his machines were so arranged that the outside coats of jars could at any time be conveniently connected to the outer circuit.

Fortunately, I did not mean or imply this either; though, forgetfully, I might accidentally have implied something of the sort, because I cannot help perceiving how much more neatly many Leyden jar experiments, recorded in books or shown at lectures, could be performed, if this mode of connecting to the outside circuit were more generally employed, instead of using a discharger worked by hand or by pulling a string. The advantage of having all the variable part of the circuit at zero potential up to the very instant of discharge, is so marked, and I have used this arrangement so frequently, that I might have been tempted to forget that it was not really a perfectly well-known, though too frequently forgotten, method. I am sure, however, that when attending Prof. Carey Foster's classes, long ago, I saw Leyden jars thus connected up to magnetising spirals or other such things; and I seem to remember also having first seen it with something of the same sort of puzzlement as to the way it acted, which I detect, or fancy I detect, in some few of the speakers, especially during the first evening, with regard to case *b*.

Many remarks have been made—and some weighty ones—on the subject of the probable absence of conducting power in clouds, and the consequent difficulty in satisfying the conditions of the B flash (*i.e.*, the impulsive rush, or spark between bodies initially at the same potential). I admit at once that obtaining B flashes from metal sheets proves nothing whatever concerning the possibility of obtaining them from clouds. But my argument is rather converse to this. I argue (whether rightly or wrongly) that flashes often occur from clouds under circumstances which, under the *a*, or steady strain, or high potential condition, scarcely seem natural. Thus points are sometimes struck and melted by flashes: and it is not easy for them to be struck in case *a*. Moreover, from a cloud violently raining flashes occur; whereas one would expect rain to lower the potential gradually. Again, from a cloud resting on a hilltop flashes occur; and sparks from a badly-insulated body are at once suggestive of impulsive rush conditions—that is, sparks from a body of zero potential. Similarly, I understand that a cloud perforated by the Eiffel Tower has carried on a thunderstorm to people below. I doubt if any of these things could easily happen under the conditions of case *a*.

But it will be said surely some of the facts you adduce establish the bad conducting power of clouds. To a great extent the Eiffel Tower case (if a fact) does. The hilltop case merely proves that the *hill* was a poor conductor. I can easily get long sparks from metals roughly uninsulated, as by wood, water, or soil.

Suppose, however, it admitted (not as proved, but as probable) that clouds are poor conductors, what then? All that we can assert is that the whole of a cloud or even a large portion of a cloud, is unlikely to discharge at once. I quite think that that is so. A calculation of energy shows that a violent flash need only discharge a very small portion—a few square metres—of a charged cloud, and that the same cloud may therefore go on sparking for a long while, as, indeed, it appears to do. Now no great conducting power is needed for a discharge from a small area at a great elevation: the lateral component of rush is in that case negligible.

Of course it *may* be asserted that clouds conduct so badly that no "flash" in the proper sense can ever occur. An answer to that assertion is the existence of lightning.

All that poor conductivity in clouds has to say concerning the impulsive rush seems to me this: that when any part of the cloud receives a violent disturbance from some A flash in its neighbourhood, that same part which receives it is most likely to spit off the consequent B flash. Whereas, with a perfect conductor, any other portion would be almost equally liable. Poor conductivity goes, indeed, to *help* the violence of the impulsive rush; for the essence of it is that a conductor of small capacity at zero potential shall be suddenly overloaded. Now if a charge suddenly communicated to a portion of a large cloud could instantaneously be shared with the whole, the potential would be reduced, and nothing very violent need occur.

This may sound like special pleading, but it is only recording the circumstances that have to be attended to. What the *facts* are must be determined by direct observation on flashes and clouds.

But let me here beseech meteorologists to remember that establishing the condition for some one flash or class of flashes does not establish the impossibility or improbability of very different conditions obtaining elsewhere or at other times. There are varieties of thunderstorms, varieties of clouds, and varieties of flashes. Every good and accurate observation will be a help to fuller knowledge, but it will take years of enlightened experience and observation before all possible varieties and circumstances of discharge can be supposed exhausted.

Before leaving this subject I should like to remind the Institution that I have never hesitated to contemplate the imperfect conductivity of clouds, whatever the consequences of that imperfect conductivity might be; and in proof of this I enclose an extract from the report of my remarks at Bath, as published in the scientific journals at the time:—

Extract from British Association Discussion.—"There was one point where Mr. Preece might have attacked him, but where he did not think Mr. Preece had made out the full strength of his case, namely, the question—What are the conditions of a flash? He (Prof. Lodge) had assumed that a flash behaves, or may behave, like the discharge of condensers in a laboratory; but it was a question whether a cloud discharge was of this kind. A cloud is not a good conductor; it consists of globules of water separated from one another by inter-spaces of air; it may be compared, therefore, to a kind of spangled jar; when a spangled jar discharges there is no guarantee that the whole of it discharges, it may discharge out in a slowish manner; it may be that you have first a bit of discharge, then another bit, and so on, so that you may have a kind of dribbling of the charge out of it, and you may thus fail to get these oscillatory and sudden rushes. At the same time he did not think that they could always guarantee doing this with cloud discharges; and it would not be safe in arranging protectors to protect for only one case, and that the easiest; they must provide for the possibility of a sudden and violent discharge. Still, the conditions of actual lightning were to be ascertained by observing lightning, and not by experiments in the laboratory."

Proceeding now to the remarks of the first speaker at the second evening of discussion, I must draw a clear distinction between Mr. Wimshurst's experiments and Mr. Wimshurst's comments thereupon.

With respect to the experiments, I feel obliged to him for exhibiting and emphasing several points which, for want of time, or otherwise, I had rather slurred over; also for recalling to my memory a little point which I had forgotten, though it is in my assistant's note book; and, lastly, for detecting an interesting matter which had escaped me.

To take these successively. 1. He seems to have exhibited side flashes, from badly earthed conductors and to well earthed bodies, more satisfactorily than in my hurry during the Paper I managed to do. It is not likely that he exhibited them so strongly as I have obtained them in the laboratory, because the violence of many of these side flashes is a thing that strikes observers with astonishment; and with a *long* conductor, as stout as you please, it makes very little difference whether its far end is "to earth" or not. It does undoubtedly make some. Prof. Threlfall, and Mr. J. Brown,

Digitized by Google

of Belfast, have both seen these effects at Liverpool, and neither, I fancy, would contemplate with equanimity the idea of bringing their knuckles near a conductor when struck, however well earthed it was.

At the same time it is perfectly true, and I must have often recorded the fact, that from a well-earthed conductor the sparks will not charge a Leyden jar. They jump in and out again. Sometimes, indeed, there is a residue of charge, but it is accidental what sign it is, and it is always merely the tail end of a series of oscillations cut off by resistance at some arbitrary point.

A more striking experiment is to connect a gold-leaf electroscope to the conductor. If the connection is metallically perfect the gold leaves are nearly quiescent. With imperfect connection they may diverge; they always slightly kick. The experiment is a little rough on the electroscope, for it strains the leaves downwards, and blows fragments off sometimes; but it is a striking thing to be able to take a ½in. or even a 1in. spark, of considerable power and noise, from the cap of an electroscope whose leaves hang stiffly down all the time and barely twinkle.

These side flashes are not very painful; they look worse than they feel; the charge hops in and out of you without going through you much or disturbing the nerves seriously. I by no means assert that a man would *necessarily* be killed if touching a conductor struck by lightning; but it would surely be a position of considerable danger.

2. The fact which Mr. Wimshurst has observed, but which I had missed, is this: that when side flashes are tried for at different points in the length of a wire joining the outer coats of two equally-insulated symmetrical jars, they are obtained more strongly towards either end of the wire, and are not obtainable at all at the middle. The middle is, in fact, a node. There are stationary waves set up in the wires, whose ends are now at high potential and now at low potential alternately, just like a long bath which has been tipped and set down sharply. To and fro the water splashes, and the ends are now at high and now at low level alternately, but the middle is a node and remains of average level all the time; it is at zero potential, and no spark is obtainable from it. It is quite an interesting fact, and one that it would have been a pity to miss. I am sure we are obliged to Mr. Wimshurst for discovering it.

3. Lastly. The little point Mr. Wimshurst has recalled to my memory is this: that when a cloud or top-plate is negative, a small terminal or point gets struck rather more easily—*i.e.*, at a lower elevation—than a big terminal or dome, even under the circumstance of the impulsive rush.

The fact is often so; but Mr. Wimshurst's account of it may lead persons who have not tried the experiment to over-estimate the magnitude of the difference, which is frequently quite inappreciable; being, indeed, often non-existent.

If the impulsive rush is violent—*i.e.*, if it proceeds from a pair of large jars, highly charged, into a plate of moderate size—the difference is non-existent. Careful measurement fails to show that the things equally struck are not all the same height; and this whether the "cloud" be negative or positive. This was the case I exhibited at the meeting, and there was no need to notice of what sign the top-plate was. But if the rush be made less violent, either by using small jars or by charging them feebly, a difference is observable. A point then gets struck, as Mr. Wimshurst showed, at a distinctly lower elevation than a knob does, whenever the overhead flash is negative—not when it is positive.*

Those are the facts, and we are indebted to Mr. Wimshurst for calling attention to them, but, as to what the moral and practical bearing of them is, opinions may differ.

Certainly it in no wise upholds the statement that points always discharge silently and cannot get struck, which is what has always been meant by their "protective virtue." Rather it would seem that they get struck in an impulsive rush always as easily as anything else, and sometimes, as Mr. Wimshurst shows, still more easily. For remember that the "striking" is not a fizz or leak of a gentle and protective kind, but is a violent and destructive flash.

The other experiments exhibited by Mr. Wimshurst are less important. One has to do with the experiment of the alternative path, or, as Mr. Wimshurst prefers to call it, a "bye-pass."

I did not make any reference to this class of experiments in the Paper, because I consider I have got to the bottom of them and thoroughly understand their conditions, which I have published; so that, except in a very serious memoir, they are not really discussable.

This may sound a desperately arrogant thing to say, but if so, I cannot help it. One would make no progress at all if one could never get to the bottom of a thing and feel one's ground secure. And I am so profoundly conscious of ignorance with respect to a vast number of phenomena that I have no care to waste time by pretending ignorance where it does not exist.

May I therefore save time by saying that all the experiments of Mr. Wimshurst on this particular matter are completely in accord with my theory;† and also that the remark of Prof. Hughes concerning the probable delay of the B spark behind the A spark is completely borne out by theory. The lag is, in fact, a quarter period of the oscillation.

Referring to another remark, I may also say that at Liverpool we have recently obtained excellent photographs of a slowly oscillating spark on a rotating sensitive disc, and that the constituent oscillations are not only conspicuous, but well spread out and accurately measurable, and in agreement with theory within one half per cent.

Finally, Mr. Wimshurst seems to have exhibited an ordinary spangled jar, in which a charge electrostatically induced in its outer coat exhibits sparks between the spangles in a simple and well-known way. He thinks this is analogous to the sparkings on the wall-gilding excited when an oscillating current is sent through a wire circuit lying on the floor; but, without laying unnecessary stress on the distinction between electrostatic and electro-magnetic induction, I think I am justified in saying that the two experiments are not analogous.

Some remarks which he made in apparent detraction of the Voss machine I do not completely follow. I am very ready to admit that a Wimshurst machine is an excellent instrument, but it is not necessary to condemn the Voss machine, or to suggest that it is worse than an old frictional machine, in order to believe that. The Voss machine I have found most excellent too, and for small size machines I personally perfer it; but that is perhaps an idiosyncracy based upon finding it easier to turn, easier to take to pieces, thoroughly under control, and mechanically simpler. There is not the slightest difficulty in telling which terminal is positive, the brush appearance to the points tells us that whenever we choose to look. Certainly it easily reverses. That is its one objection; and occasionally it is an annoying peculiarity, though I have got pretty used to it.

I should like to remark here, what after all is fairly obvious, how great service has been done by the developers of the modern influence machine, from Nicholson, Varley, and Thomson, to Holtz, who did so much, and on to Mr. Wimshurst himself.

Many of the remarks of Professor Hughes I have already incidently answered or referred to. He says, quite rightly, that I maintain flat ribbon and plenty of surface is an improvement on round rod, but as to whether it is a matter on which very great stress need be laid, I will defer discussion till I come to the observations of the President.

Prof. Hughes' experiments on iron *versus* copper no doubt agree with mine whenever he uses alternating currents of the same frequency, and disagrees when he uses alternating currents of much lower frequency. For telephonic frequencies iron has much greater impedance than copper. Oliver Heaviside does not for an instant deny this, but he says that there may be circumstances in which this extra inertia is an *advantage*, in that it helps to preserve the character, or quality, or shape, of electric waves, although it admittedly transmits more slowly and weakens them. If Mr. Preece and observers in America find in practice that copper wire is better for telephony, as they apparently do, then that means that the character of the vibrations is *sufficiently* preserved in copper, and the comparative absence of retardation is all to the good. It may, however, still happen that in submarine cables iron will show an advantage. It is a curious paradox, no doubt, at first sight, and whether the advantages outweigh the disadvantages in any particular case is a quantitative question of no extreme simplicity though, nevertheless, it has in general terms been worked out.

But the question for ordinary Leyden jar frequencies is much simpler. For them the *impedance* of iron and copper of the same diameter is practically the same, unless the wire is very long or very thin. The *resistance* of the iron is much greater than that of the copper. All this can be expressed, and has been expressed quantitatively, with, in my opinion, complete certainty, and beyond the reach of any but revolutionary doubt to which all scientific doctrines are liable.

And on the practical side one may say this: The circumstance of a telephone wire and of a lightning rod are not only different, they are, in some respects, opposite. The object of a telephone wire is to convey electric waves, unaltered and unweakened, to a distance. One object of a lightning conductor is to wipe them out and dissipate their energy as soon as possible. The very properties which are detrimental in one case may be desirable in the other. It is no doubt a quantitative question how far it is wise to wipe out energy in the lightning conductor itself, and Major Cardew thinks it is unwise to do so at all. Possibly; but at present I hold that so long as total impedance is not appreciably increased, and so long as the margin of melting is not too closely approached, so long it is desirable to dissipate energy wherever you can and to check the violence of the oscillations as rapidly as possible; and hence I hold that a moderate amount of true *resistance* is no defect in a lightning conductor.

Everyone must admire the beautiful method by which Prof. Hughes tests his wires for circular or cylindrical magnetisation.

(To be continued.)

M. LEBLANC'S ALTERNATE-CURRENT MOTOR.*

Alternating currents present some peculiar advantages in the transmission of energy, for they are more easily handled under high tension, and they do not affect the insulation in the same way as do continuous currents. The phenomena of self-induction have hitherto hindered us from realising a motor capable of self-starting and of running at any required speed, whilst at the same time possessing a high efficiency and a considerable output per unit weight. It is thought that these advantages may be realised in the following manner:—

My motor consists of—(1) a fixed armature in the form of a ring; (2) a movable field magnet in the form of a Gramme or Pacinotti ring placed in the interior of the armature and furnished with a collector; (3) a small alternate-current dynamo [or motor] with permanent magnets, whose armature is mounted upon the axis of the machine. This armature is connected in series in the circuit of the first armature, and receiving the current from the line turns synchronously with the generator. Its purpose is to rotate a certain number of pairs of brushes, which rest upon the commutator of the moving field magnet. The number of these brushes is equal to the desired number of field-magnet poles and proportional to the number of alternations of the current which feeds the machine. They are all connected amongst themselves by a short circuit.

Theory and experiment demonstrate that in these conditions—(1) a current always in the same sense is developed in the moving ring [the field magnet], and completes its circuit by traversing the brushes after having excited the field †; (2) a motor couple (torque) always in the same sense (a function only of the intensity of the alternating current traversing the armature and of the speed of the brushes relatively to that of the collector) is determined upon the axis of the ring. The machine is self-starting, and the rotation is in the same sense as that of the brushes. The torque developed upon its axis diminishes proportionately as the velocity increases. As to the work furnished, it is a maximum when the speed of the armatures is equal to one-half that of the brushes.

The armature which has been employed in these experiments was taken from a Rechniewski machine. We have made the brush-holders movable, and the method of gearing obliges them to ma e one-half a revolution during one alternation of the current.

Theory shows that the electrical efficiency of this machine may be made as high as we please, and that the ratio of the E.M.F. which is necessary to send the alternating current through the armature to that which would be required if the self-induction coefficient were zero is very nearly unity. This is due to the fact that the current is not reversed at the same moment in each of the field-magnet coils, but successively in the coils of the Gramme or Pacinotti ring, and, moreover, the reversal takes place at that moment when each coil is solely traversed by that number of lines of force due to its own self-induction. Everything happens, therefore, as if the coefficient of self-induction of machine was reduced to that of the armature alone, and the counter E.M.F. due to the reversals of the alternating current is very small compared with that which is absorbed in the production of work. We expect in this way to obtain an alternating motor which, whilst permitting us to take advantage of the properties of such currents, shall also have as high an efficiency and as large an output as an ordinary continuous-current machine. The type of machine to which we have been led, and which can receive an infinite number of different forms, necessitates no larger number of parts than do ordinary alternating dynamos furnished with separate exciters such as are already in daily use.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 25, 1889.

During the past week the daily papers have been devoting column after column to the weary investigation now going on before a referee with the object of determining whether the infliction of death by means of electricity is a "cruel and unusual" method of execution. The questions propounded to the different witnesses by the examining counsel for the condemned criminal Kemmler have been very much the same as those asked for the past few weeks, the monotony being varied only by the divergence of opinion which seems to exist on those questions. Probably the most interesting information gleaned last week was obtained from Commodore Gerry, one of the Commissioners on whose report the law was adopted. In the course of Commodore Gerry's examination it transpired that the committee had considered 41 methods of inflicting death, but at last weeded these down to four, namely, the guillotine, the garrote, poison and electricity. The first was rejected because of its traditions and its ghastly connection with the French Revolution; the garrote, which was very effective and had much to recommend it, was used by only one civilised country, Spain, and was, moreover, a relic of barbarism, and disfigured the criminal. Prussic acid was considered, but death from it was not deemed certain, as it became decomposed, and, moreover, the smell was dangerous to those who handled it. It also required to be administered by a man of considerable medical knowledge, and no one of sufficient ability, it was claimed, would consent to become public executioner. Morphine was also suggested, but the difficulty was to find what dose would prove fatal in each case, and the medical profession protested against the prejudice it might cause in the public mind. The fourth method, electricity, was finally decided on, and the Commission issued circulars and sent them to the various judges and doctors throughout the State, asking them which of the four methods named they thought better than hanging. 275 answers were received. Of these 81 thought hanging good enough, 75 advocated electricity, and the rest were scattered. Considering this admission of the manner in which the final determination was arrived at, it seems rather cool that the opinion of electricians should not have been consulted on the proposed method in the same way as the proposed execution by means of narcotics and poison was submitted for approval to the medical men. It would be only fair to suppose that if this had been done the verdict would have been almost unanimous against electricity amongst those who come in daily contact with it. Amongst the various witnesses who were called last week was Mr. Francis W. Jones, electrician of the Postal Telegraph Company, who testified as to the varying resistance of the human body, measured under different conditions. Dr. Landon C. Gray, professor of nervous diseases, was also of opinion that electricity was an uncertain means of killing. The testimony of a man who had been struck by lightning was also taken, to show that a current of electricity, even in the shape of lightning, does not inevitably produce death. Among the witnesses also called this week was Mr. T. A. Edison and Mr. A. E. Kennelly. Mr. Edison was decidely of the opinion that 1,000 volts of alternating current could be depended on to do the work surely and effectively, but when asked the stereotyped question, "What do you base this opinion on?" he admitted that it was merely an opinion and not based on the results of observation, as, indeed, was self-evident.

Now that Canada has its trans-continental railroad and telegraph system, it is looking about for further extension of its facilities for communication, especially with the outer world, and the latest project advanced is the laying of a Canadian trans-Atlantic cable. Various arguments are brought forward to show that such a cable has a *raison d'être*, but it is probable that the existing cable companies will hardly see it in the same light. It is proposed to lay the cable on an entirely different route from those existing at present, most of which are laid around the banks of Newfoundland, the furthest north being the Anglo-American cables which run from Heart's Content to Valentia. It is proposed to lay the new cable still further north—from Greenly Island through the Straits of Belle Isle, straight across to the nearest point in Ireland, taking a course nearly due east and west. This route is claimed to be 150 miles north of any Atlantic cable now laid, and the depth of ocean is also said to be considerably less, so that any interference with other cables is out of the question, and repairs could be very easily made. The company would only have to provide and maintain a main cable of 1,900 miles in length, the connection at the eastern terminus being with the Government, Post Office, and telegraph service, and at the western end with the Canadian Government telegraph service at Greenly Island

* Paper read by M. Leblanc before the French Academy, July 29th, 1889 (*Comptes Rendus*, Vol. CIX., No. 5).

† [As this current is induced by the alternating current in the fixed ring armature, the description would be clearer to the English reader if the terms "field magnet" and "armature" as used in the text were reversed.—ED. *E.*]

Digitized by Google

and with the Straits of Belle Isle. The cost of this cable is estimated at about $1,600,000, and it is said that one of the principal cable manufacturing concerns in London has tendered to lay the same for the sum of $1,500,000. With this low cost of cable and the other advantages above-mentioned, it is claimed that sufficient reasons exist for carrying out the proposed enterprise, but with ten cables now landing in Canada the actual necessity for another seems somewhat problematic.

The gravity battery has been so long and so well known, and so many modifications have already been made upon it in order to overcome certain defects which are inherent in the battery, that it would seem difficult to conceive of anything new in this field; but it appears that a very simple and decided improvement has been made by Mr. P. B. Delany, whose synchronous multiplex telegraph system is already known to your readers. Briefly stated, Mr. Delany overcomes a number of inconveniences attending the use of the gravity battery by covering the zinc with a porous material, and likewise inserting the sulphate of copper in an envelope. Thus he encloses the zinc in a paper envelope, and the sulphate of copper crystals in straw-board box. When the zinc is so enclosed the covering protects it from the hydrogen gas which constantly arises from the electrode, carrying with it sulphate of copper. The covering also prevents stalactite formations of copper on the zinc, which occur in the ordinary gravity battery, and goes down into the solution of sulphate of copper, solidifying it so as to frequently render the removal of the copper electrode difficult without breaking the jar. The covering also retards the dissolving of the sulphate of copper and an unnecessarily free action upon the zinc, and wasteful supersaturation. Mr. Delany has found by actual test that after three or four days, when the two elements, sulphate of copper and sulphate of zinc, have been produced to a proper working extent, the resistance of the battery is no higher, and the current is even greater than with batteries of the ordinary form. Another little improvement introduced by Mr. Delany relates to the prevention of creeping salts in batteries. In order to avoid this the inner lip of the jar is coated with asphalt varnish, to which ordinary white sand is applied, thus leaving a rough surface. This surface, it would seem, breaks up the crystals, and, indeed, prevents them rising above the lower edge of the roughened surface. Of 100 cells in Mr. Delany's office thus treated six months ago, not one shows the slightest trace of salt creeping, as I have had occasion to witness myself.

Mr. Rankin Kennedy's work in the department of alternating currents, which is no doubt well known to your readers, will shortly, it would seem, play quite a prominent part in the litigation which is about to be commenced on this side of the water by the Westinghouse Company in support of their claims to control the alternating system of distribution. The suits which it is said are about to be brought are based on a patent granted last week to Mr. Rankin Kennedy and assigned to the Westinghouse Company, which it is claimed covers the multiple arc method of distribution by means of transformers. The patent contains but a single claim, which, in view of the importance attached to it, it may be interesting to your readers to see in full, and I therefore give it herewith.

"The method of distributing and regulating alternating electric current by secondary generators, which consists in producing in two or more derived circuits constituting the primaries of two or more secondary generators a counter E.M.F., which, when any secondary is opened, is practically equal to the applied E.M.F. in the primary, and in controlling said E.M.F. by the current flowing in the corresponding secondary, when the secondary is closed, in such manner that the current in the primary shall vary with, and be approximately inversely proportional to, the resistance in the secondary, substantially as described."

As I mentioned some time ago in this letter, a patent has been recently issued to Mr. Weston on the construction of armature cores by means of laminated plates insulated from each other. Grave doubts have, however, been expressed by parties using this form of armature as to the validity of this patent, in the face of previous work done in this direction. In alluding to this, a correspondent in one of the New York electrical journals cites a passage appearing in an English journal, published in 1873, as a translation from the *Comptes Rendus* of the Académie des Sciences, Vol. LXXVII., No. 9, in which M. A. Pellerin, in a note on the Siemens' bobbin, refers to the heat developed in the same when made solid, but shows how this had been avoided by constructing the armature of discs of soft iron insulated from one another. This would seem to be clear in its application, but considering the glorious uncertainty which has heretofore characterised electrical litigation, no one can hazard an opinion on the outcome of a legal test.

Nearly all vessels which have lately passed over the course usually taken by the Transatlantic steamships have reported the sighting of icebergs, and the collision of the "Saale" with one of these has again revived the question of the avoidance of danger from this source. Among the various methods proposed for detecting the presence of icebergs in time to avoid danger those involving the application of electricity seem to be in the large majority. Most of these methods are based on the lowering of the temperature of the water due to the presence of the iceberg, which decrease in temperature would be indicated by some thermostatic arrangement in connection with an electrical indicator of some kind. This idea, though very pretty in theory, cannot, however, be relied upon in practice, as pointed out by Mr. F. R. Colvin, in an article published in the *Electrical World*. As Mr. Colvin puts it, the indications of such an instrument would depend entirely on the direction of the currents surrounding the iceberg, both at the surface and below, and also, evidently, on the direction in which a ship approached the berg. Thus, if the cold current were flowing towards the ship the indications would probably be given in time to avoid a dangerous collision, which, again, would also depend upon the tactical diameter of the ship. But, on the other hand, if the ship approached the iceberg in the same direction in which the cold current was flowing from it, the instrument being relied upon for timely warning would, of course, fail to operate, and would thus be more a source of danger than a safety device. The field, therefore, is still open for the ambitious inventor.

Electrical welding has been making satisfactory advances in this country, and quite a number of wire and cable makers have adopted the process, among them the Trenton Iron Company of Trenton, N.J., and the well-known firm of Roebling and Sons. A recent important advance in this method of welding is reported, and consists in the actual welding, end to end, of the two sections of a cable containing no less than 55 strands. The cable, which consists of hard-drawn low carbon steel, was so manipulated that each strand was directly welded to the one opposite to it in the two sections, so that the finished joint occupied no greater area than that of the original section. The tensile tests of the welded cable give the most perfect results, the maximum tensile strength of the welded specimens averaging from 80 per cent. of the maximum load of the original section. Severe bending and twisting tests give an equally good result, the cable resisting bending back and forth many times through an angle of 180deg. at the weld. The important advance achieved in this direction will be appreciated by engineers, and cannot fail to extend the use of the cable in construction work considerably.

No event of importance occurs now-a-days but the electrician is called into service, and the late great Sullivan-Kilrain prize-fight was no exception to the rule. As the precise location of the battle-ground was kept a profound secret in order to avoid police interference, the regular telegraph service could evidently not be depended upon to furnish the news with sufficient promptitude. The New York *World*, however, with its usual enterprise, in order to obtain the first news regarding the battle, had arranged to run a telegraph line from the battle-ground to the nearest wires. For that purpose they had rigged up several miles of wires on reels, with posts that could be quickly erected, instruments, &c.—in fact a small field telegraph system, which was actually in satisfactory operation shortly before the fight began. But their labours unfortunately went for nought, for, just as the fight was about to begin, the main-line wires were cut, thus, of course, cutting off all communication. As a stroke of enterprise, however, the fact is worth mentioning.

CORRESPONDENCE.

THE INDUCTANCE OF UNCLOSED CONDUCTIVE CIRCUITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In my communication to this journal on "The Mutual Action of Rational Current Elements," *The Electrician*, December 28, 1888, p. 229, I described the meaning of, and gave the formula for, the mutual energy M of a pair of rational current elements.

Thus, let C_1 and C_2 be their moments, r their distance apart, ϵ the angle between their directions s_1 and s_2, μ the magnetic inductivity of the medium (uniform), and M the mutual energy. Then,

$$M = \mu C_1 C_2 \left(\frac{\cos \epsilon}{r} + \tfrac{1}{2} \frac{d^2 r}{ds_1 ds_2} \right) \quad . \quad . \quad . \quad (1)$$

It follows immediately from this that the mutual inductance of any two linear circuits is

$$M = \mu \int\int \left(\frac{\cos \epsilon}{r} + \tfrac{1}{2} \frac{d^2 r}{ds_1 ds_2} \right) ds_1 ds_2 \quad . \quad . \quad . \quad (2)$$

M being now the mutual inductance. If the circuits are closed the second part contributes nothing, and we have

$$M_0 = \mu \int\int \frac{\cos \epsilon}{r} ds_1 ds_2 \quad . \quad . \quad . \quad (3)$$

the common form of Neumann's equation, with the μ prefixed to adapt it to Maxwell's theory.

But if the lines are unclosed, then, according to my description of the nature of a rational current element, the linear currents become closed by means of currents uniformly diverging from their positive ends, and uniformly converging to their negative ends. The second part of (2) is now finite. Let P_1 and P_2 be the positive poles, N_1 and N_2 the negative poles of the linear currents, and let the value of the second part of (2) be M_1. It is given by

$$M_1 = \frac{\mu}{2} (P_1P_2 + N_1N_2 - P_1N_2 - N_1P_2) \quad . \quad . \quad (4)$$

where P_1N_2 means the length of the straight line joining P_1 to N_2, and similarly for the rest. We may, therefore, calculate M by Neumann's formula, applied to the linear circuits, and then add the correction (4) to obtain the complete expression.

A practical application is to the theory of a Hertzian oscillator, at least of a certain kind. Let a straight wire join two conducting spheres, or discs, &c. Imagine an impressed force to act in the wire, and to vary in any not too rapid manner. The current will leak out (or in) from (or to) the wire as well as the terminal conductors, but if they are relatively large nearly all the current will go across the air from one terminal conductor to the other, and we may ignore the wire leakage. The permittance S is then that of the dielectric between the two spheres (say), and is quite definite. Also, if the changes of current are not too rapid, as mentioned, the current in the air will follow the lines or tubes of displacement. The inductance L is therefore also quite definite, in accordance with Maxwellian principles, so that the natural frequency of oscillation of the condenser-conductor circuit can be calculated with considerable precision from the dimensions.

If, as an illustrative approximation, we suppose the current to come from the centre of one sphere and go to that of the other, and then diverge or converge uniformly, we have to find the inductance L of a straight wire or tube of length l and radius a, with terminal continuations as before specified. In a Paper in the July *Phil. Mag.* Prof. Lodge calculates L without any allowance for the current in the dielectric, viz., by Neumann's formula (3). We have therefore only to examine what the correction (4) amounts to.

In the case of two very close parallel lines, we may put

$$P_1P_2 = 0 = N_1N_2, \text{ and } P_1N_2 = P_2N_1 = l$$

so that the correction is simply $-l\mu$. That is, if the dielectric current is ignored, (3) overestimates M by the amount μl. The same applies when it is the inductance of a straight tube or solid wire that is in question. Deduct its length in centimetres from the uncorrected to obtain the true value, in C.-G.-S. electromagnetic units, *i.e.*, centimetres.

Prof. Lodge (*loc. cit*) also gives the formula which Hertz says Maxwell's theory gives. On making the comparison, I find it is equivalent to adding, instead of deducting l, from the result of Neumann's formula.

Perhaps Mr. Preece, who has distinguished himself by his experimental measurements and calculations relating to the coefficient of self-induction of straight wires, would give his opinion upon this point.

It should be remarked, as an essential condition of the validity of the process described above, when practically applied, that the changes of current must not be too rapid. When the changes are slow the immense speed of propagation of disturbances through the air causes the electric displacement at any moment in the neighbourhood of the vibrator to be very nearly that which would obtain according to electrostatic principles, and the current to follow the tubes of displacement. But go to the other extreme, and imagine the changes to be so rapid that waves, whose length is a fractional part of the length of the vibrator, are produced. It is then clear that the theory would not apply at all, neither as regards the inductance nor the permittance. Now Hertz, in that series of brilliant experiments which have gone far towards practically establishing the truth of Maxwell's inimitable theory of the ether considered as a dielectric, employs sometimes waves which are not very much longer than the vibrator itself. Only close to the vibrator, therefore, do we have the electrostatic field (approximately) predominant, and we may expect a sensible error in applying the electrostatic theory. It is, however, quite easy—in fact, easier—to use longer waves. But in any case, the *exact* calculation of the permittance and inductance of a vibrator involves a good deal of mathematics to find relatively small corrections.—

Yours, &c., OLIVER HEAVISIDE.

July 21, 1889.

ALTERNATING MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having read with great interest your able leader on Alternate-Current Working, may I go so far as to disagree with some of the remarks you make, giving my reasons? So far from the old theory of alternating motors being non-existent or vague, it is perfectly clear—namely, that an alternating motor with back electromotive force equal to or greater than the dynamo, can only work as a motor by virtue of its self-induction. Mr. Mordey denies this, but does not say how it does work. The analogy with a direct-current motor in misleading. A direct-current motor has less electromotive force than the generator, and controls itself by variation of speed. The demagnetisation of the field of an alternator by the current is perfectly well known to dynamo makers. The effect of the armature current may be divided into cross induction and back induction, to use my own terms. The cross induction is taken into account by Prof. Thompson when he makes his coils to suit, and the back induction is taken into account by every maker who puts on extra field excitation to neutralise it. I think the questions have also been discussed by Dr. Hopkinson in Royal Society Papers. As far as the field is considered, cross induction, and more especially back induction, are permanent effects. You say the experiment of the 2,000 and 1,000-volt machine is not a proof of the great self-induction of the machines, because it can be explained as weakening and strengthening the fields, but that is simply self-induction under another aspect. When I spoke at the meeting I did not think of it as weakening and strengthening the fields; but I objected, as I always have done, to the loose way in which the term self-induction is commonly used. A Paper man appears to think of electrical inertia, or self-induction with a constant coefficient; and a great many dynamo men—I among others—prefer to consider the whole electromotive force generated one way or the other.

Mr. Mordey's experiment with the 2,000 and 1,000-volt machines seems to have confused people hopelessly. It is not

Digitized by Google

a parallel-motor case at all, and most of the conclusions drawn from it must be reversed to have any meaning.

I would like to put an elementary case: Assume no self-induction in the armature circuits. Take two similar machines of equal E.M.F. Imagine them cophasedly synchronised. No current passes, and no work is done on or by either. Lessen the field excitation of one. It is at once a motor at every part of the period, except at the points of zero current. If no load is on it will lead, and its lead will increase till it is a quarter of a period ahead of the dynamo. The two machines are practically short-circuited then. The motor gets equal impulses backwards and forwards. If load is put on it reduces its lead so that the backward impulses are less, and forward greater, till it is cophasedly synchronised. Such a motor is really only capable of use on a series circuit, and such a series motor gives a good full load when the current is forced through it when cophasedly synchronised—that is, on a constant-current circuit. At no load the armature loss is as great as at full load. I explained this in 1887. A motor with small E.M.F. cannot, therefore, be used on parallel mains, for at no load it tries to short-circuit them. If its E.M.F. is just under the main E.M.F. enough to let the full load current go through at full load, the current obviously increases enormously at no load. When working off a single dynamo of course this effect is masked.

The action of two similar machines of equal and opposite E.M.F. is much more difficult to put clearly. Suppose them cophasedly synchronised. Then make one lag. At some instants each is acting as a dynamo, and at some as a motor. The current at any instant is equal to the sum of the E.M.F.s divided by the resistance, when they are in the same direction, and to the difference when they are opposed, as they are most of the time. Any instant when one is a motor has a corresponding instant when the other is a motor, so there is no control. The system is perfectly symmetrical, and both do equal work on their armature resistances. We are assuming the fields constant. Leave the field excitation constant, banish coefficients of induction and curves of sines from the ideas, but assume that the armature currents may weaken or strengthen the fields as the case may be. Think of the leader first. As a conductor comes into the field it generates E.M.F. and produces a current. If it worked on resistance the current would be at a maximum when the conductor was half-way past the pole, and would fall correspondingly afterwards; the lagging machine interferes, however, and by its lagging but opposed E.M.F. it stops and reverses the current before the conductor is much past the middle of the pole. In fact, the current due to the machine comes sooner than if it were produced by the leading machine, and later if produced by the lagger. A current lagging after the E.M.F. weakens the field, and a current preceding the E.M.F. strengthens it. The leading machine, therefore, has its field strengthened, while the lagger's is weakened; the lagger thus becomes a motor. It seems a common error to suppose that in driving a motor the dynamo current lags because there is self-induction; it really leads.

Exactly the same result could be got by treating the machines as having unaffected field magnets and constant coefficients of self-induction and curves of sines.

In parallel running the lagging dynamo need not suddenly turn into a motor, all that is needed is for its load to be reduced.

A perfect motor could be got without the armature weakening of the field, or cross or self-induction, if the field could be weakened artificially, as in the hypothetical case taken before. A 100-volt motor would just have its field weakened till it took its full load current without lagging, and would then give the same output as when used as a dynamo or resistance. When the E.M.F. is equal and lagging is necessary, the current should be as nearly in opposition to the opposing E.M.F. as possible. As far as I understand what you and Mr. Mordey mean by a "stiff" field, just the opposite is required, and the 2,000 and 1,000-volt experiment show that is just what Mr. Mordey has really got.

I do not quite know what is meant by the "vital point being the relation of the stability of synchronisation upon the armature inductance." It sounds very much like the old theory, that you want to keep your machines together with the least waste of power over armature resistance. But it is an impressive way of saying something. The main drawback to an alternating motor is that its armature current is at the wrong time, so that the armature loss is heavy in proportion to its output. Mr. Mordey never gave his armature currents.

I must say I do not think we will get much further if self-induction and armature reactions are sometimes mixed up and sometimes separated, and I really doubt whether an army of third-year students, glittering with secohmmeters telling us how many of Profs. Ayrton and Perry's things there are in each stationary armature, will get information fit for anything better than a Paper.

I do not wish to attack Mr. Mordey more than necessary for giving my own views clearly. I do not really understand his alleged ideas fully enough to go into them. One of us must have talked a great deal of nonsense.—Yours, &c.,

JAS. SWINBURNE.

[This letter having arrived only just in time for the present issue, we must defer any reply until next week. Meanwhile we shall be glad to hear from other readers upon the subject.—ED. *E.*]

THE USE OF CARBONATE OF SODA IN SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with much interest the published report of Mr. Wm. H. Preece's Paper on "Secondary Batteries," read before the Society of Arts on May 1st, 1889.

The use of carbonate of soda in the electrolyte in order to prevent sulphating, according to my experiments, is attended by serious difficulties not mentioned by Mr. Preece.

If the battery is in constant use a grey precipitate rapidly forms, which falls to the bottom of the jar. It is apparently a sodic-sulphate of lead, and a non-conductor, but particles of active material become incorporated with it, and soon short-circuit the battery. I have seen a cell become one-third filled with this precipitate after a few week's use.

This precipitate also softens and disintegrates the active material, and the apparent advantage of its use in preventing sulphating seems to be off-set by the disadvantages above mentioned.—Yours, &c.,

SAMUEL F. BARRY.

New York, July 25, 1889.

MODES OF DAMAGE BY LIGHTNING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Kindly permit me to ask Prof. Lodge to state the actual height of the church steeple at Wavertree, as it has an important bearing on the question of area protected by an efficient lightning conductor. That the conductor is efficient may, I presume, be taken for granted; but it appears to me that the points A and C in Fig. 1 (elevation of Mr. Lennox Peel's residence, *The Electrician*, July 12) may be outside the area of protection, as commonly accepted—viz., a cone, the finial point as apex, and radius of base being equal to the height of finial point. May not the damage to house roof, guttering, &c., have been caused by a direct stroke, which, owing to the lessening of atmospheric resistance caused by the approach of the charged cloud, was enabled to discharge itself through this path before coming within striking distance of the conductor?

Of course I do not offer this as an original idea, but there does not appear to be any circumstance mentioned in Dr. Lodge's report antagonistic to this old theory.

The fusion of gas pipe in cellar may also be due to this discharge.

If, however, the fusion was not caused by an electrical discharge jumping from or to the pipe at point of fusion, but was caused by the same disturbance which caused the luminous display on the drive, might it not be due to either a direct stroke received by the conductor on steeple, or the heavy induced currents, or rather waves, which would probably be surging in the conductor? It is probable that the whole of the

Digitized by Google

pipe system in the vicinity would be affected; that the ball of fire travelling up the drive was merely the luminous discharge given off from the gas pipe; and that the fusion of pipe in cellar was due to a fault in the same, it having been partially cut by a gas hook, perhaps (if lead), or having heated at a white-leaded screwed joint (if iron). Or it may be that this was the weakest point, conductively (if I may coin a word), and therefore gave way.

Allow me to put on record the following instance of a luminous discharge:—

The Manchester Racquet and Tennis Courts, situated in New Blackfriars-street, has a brick shaft rising from the centre of the block of buildings, and supporting an iron ventilating pipe, some 12in. or 14in. in diameter and 45ft. long; a 6ft. elevating rod and five point finial is fixed on the ventilating shaft, and a seven-strand half-inch copper rope is carried down by the side of the iron pipe, and is lashed to the latter at intervals of about 5ft.; at the bottom of shaft the rope enters the ground, and is carried some 70ft., terminating at the main branch water pipe. About four years since I happened to be walking down New Blackfriars street and noticed a brilliant blue, lambent light surrounding the finial points, and apparently extending some four to six inches in every direction around each of the five points.

There was at the time a background of dense black cloud, extending from the horizon about 45deg., and another dark cloud bank coming up. A thunderstorm had passed over an hour or so before. I watched this brush discharge for about twenty minutes, when it gradually disappeared, occasionally brightening up, then again fading, till at the expiration of half an hour or thereabouts the approaching storm broke, with a prelude of a few heavy drops of rain. I saw no more of the discharge after this, though I waited till the storm was nearly over, hoping to see the conductor receive a lightning discharge, but was disappointed.

The lightning was exceedingly vivid, and was accompanied with heavy peals of thunder, and the storm was directly overhead, or in the immediate vicinity, flash and peal being apparently simultaneous. I have omitted to state that the luminosity was so intense that the points were imperceptible for about half their length (6″ points, as usual, with an 18″ central point) and that it had the appearance of St. Elmo's fire as seen on the yards and rigging of an iron ship, except that the edges appeared to be of a reddish-yellow tinge; but this was probably owing to smoke from adjacent chimneys passing across the line of vision.

With reference to Colonel Fraser's report on the Mangalore Lighthouse disaster, I cannot agree with him that "the earth connection must have been complete."

Two hundred feet of cable, laid on an insulator (rock), even though wet with heavy rain, would form but a poor "earth."

Allow me to quote an instance of the insulating virtue of rock—porous wet sandstone. I fixed a lightning conductor on a boiler chimney, belonging to Messrs. Emmott, of this city. The conductor was of 1in. by ⅛in. copper tape, entering the ground (tipped stuff on substratum of red sandstone) at the base of chimney, and extending some 70ft. to the river Irwell; a copper plate 2ft. by 1ft. being rivetted and soldered to the tape and sunk in the river.

A copper plate, 1ft. by 1ft., was buried in the ground, at about 6ft. from the river bank, and 5ft. deep, to form a testing earth; but on testing, the earth resistance was found to be over 2,700ω; a second testing earth was formed by burying a similar plate flat on the substratum of sandstone, and covering it with a bushel of coke, well settled down with soil and water, but still the R was over 2,700ω; how much over I am unable to say, as I had not the means available of measuring any higher resistance.

The fact that water offers a high resistance appears to be too frequently overlooked. Compared with rock, of course, it is a good conducting medium, but by itself, without the admixture of earth of some kind, it is a poor conductor. If Dr. Lodge or Mr. Preece would lay stress on this point, probably we should hear less of lightning conductors being "earthed" in slate cisterns, specially erected and insulated, evidently with the intention of drowning the lightning; or of brick sumps specially constructed and cemented to prevent the escape of water by percolation, so that the conductor may always terminate in this valuable, but greatly imposed on, fluid.

I must apologise for taking up so much of your valuable space. I had no intention of writing at such length, but the importance of and general interest taken in this subject must be my excuse.—Yours, &c. J. Lavender, Junr., C.E.

11, Todd-street, Manchester.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

Note.—The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.

COMPANIES' MEETINGS & REPORTS.

The Cuba Submarine Telegraph Company (Limited)

The thirty-sixth ordinary general meeting of the Cuba Submarine Telegraph Company (Limited) was held at the Company's offices, No. 58, Old Broad-street, on Wednesday last, Mr. Alexander F. Low presiding.

The SECRETARY (Mr. James Scott) read the notice convening the meeting. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: In moving the adoption of the report I have much pleasure in congratulating you on the nature of the results of the last half-year's traffic, which I am sure will be highly satisfactory to you. The receipts are £888 in excess of those of the corresponding period of the previous year, and £3,000 in excess of those of the corresponding period of 1887. The charges, I am sorry to say, are exceptionally high, caused principally by the expenditure of £1,600 in repairs on the Batabano-Cienfuegos cable; but the amount of money left at our disposal is sufficient for the payment of the interest on the Preference Shares, for the payment of a dividend at the rate of 9 per cent. on the Ordinary Shares, for placing £6,000 to the reserve fund, thereby increasing it to the good round sum of £90,000, leaving £345 to be carried forward to the current half-year. Since our last meeting we have been getting a number of messages from a French Company, who have established communication between Cuba, Hayti, and Venezuela, which we hope will go on increasing, and if so, we may expect that they will make up for the reduction we have made in our charge. We have had very serious complaints from the West Indian Colonies for a long time as to our high charge, and we have thought it incumbent upon us to make a reduction for transit messages. You will not be surprised to see by the report that we have come to the resolution of making an inroad upon the reserve fund by laying a duplicate cable between Batabano and Cienfuegos. This was the original cable laid in 1870, and it is now 19 years old, and, as you learn from the report, it is far from being in a satisfactory state. Therefore it is incumbent upon us as quickly as possible to duplicate it. We cannot now give an estimate of its cost, for Mr. Keith, who has been very much occupied upon the repairs, has not been able to furnish us with the probable length of the cable that will be required. We are, therefore, not in a position to ask for estimates for the new cable. The breakdown which occurred on the 13th of last month was successfully restored on the 27th. With these remarks I beg to propose—

"That the report and accounts for the half-year ended 30th June last, now submitted, be received and adopted."

Mr. THOMAS GREENWOOD seconded the motion.

Mr. COCHRAN: Will you kindly tell us what will be about the length of the new cable?

The CHAIRMAN: About 170 miles. It is the only cable we have had in that section. We have had three in the other—from Santiago to Cienfuegos. One of those was abandoned nine years ago, but the other two are in good working order.

Mr. GRIFFITH desired to know what had been the result of the last five weeks' traffic since the reduction in the rate took place?

The CHAIRMAN: We cannot answer definitely the question you have asked because we have only had a month's working, but I am happy to be able to inform you that the traffic for that month is estimated to produce within £80 or £90 of the amount we received from the traffic of July last year, so that there is very little falling off caused by the reduction of the rate.

Mr. HOOPER: What is the average reduction of the rate?

The CHAIRMAN: The principal reduction is on the transit messages from the West Indies. Our rate was 67 cents, and it is now reduced to 50 cents—a very considerable difference, but not more than the circumstances demanded.

Mr. HOOPER: Have the other lines made a similar reduction?

The CHAIRMAN: We were fortunate in making application to the International Company soliciting them to do so, and they reduced the rate on their line—not exactly so much as we did.

The resolution was then unanimously agreed to.

The CHAIRMAN then moved:—

"That the following dividends for the half-year be now declared upon the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income-tax, on the Preference Shares, and 9 per cent. per annum, free of income-tax, on the Ordinary Shares, payable on and after to-morrow."

Mr. GREENWOOD seconded the motion, which was carried unanimously.

The CHAIRMAN moved the next resolution as follows:—

"That Mr. Neil Bannatyne be re-elected a Director of the Company."

Mr. Bannatyne, he regretted to say, was suffering from illness, which prevented his attendance on that occasion; but that gentlemen expected to be able to resume his usual duties within a week or a fortnight.

The motion having been seconded by Mr. GREENWOOD, was carried unanimously.

Mr. C. W. PARISH proposed:—

"That Messrs. Gane and Jackson be, and they are hereby, re-elected auditors of the Company for the current year at a salary of 20 guineas."

Mr. HOOPER having seconded the motion,

Mr. BOVILL proposed as an amendment that only one of these gentle-

Digitized by Google

men should be re-appointed, on the ground, as he contended, that then there would be no division of responsibility. He preferred to have the responsibility on the audit fixed upon an individual rather than upon a firm, because the shareholders in that case knew what they were doing.

Mr. GRIFFITH seconded the amendment, maintaining that the law had always a greater hold on an individual than on a firm.

After a brief discussion,

Mr. PARISH agreed to withdraw his motion in deference to the wishes of some of the shareholders, and the amendment was carried re-electing Mr. Gane as auditor.

The CHAIRMAN subsequently proposed a vote of thanks to the secretary, to Mr. Keith, the Company's engineer, and the members of the staff in London and in Cuba, paying a warm tribute to their zeal and efficiency in performing their various duties.

Mr. BOVILL having seconded the resolution, it was cordially carried.

The SECRETARY briefly acknowledged the compliment, remarking that it would be very gratifying to all concerned to know that their services met with the approval of the shareholders.

A vote of thanks was afterwards passed to the Chairman, who briefly returned thanks, and the proceedings terminated.

United River Plate Telephone Company (Limited).

The third annual ordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street, under the presidency of the Right Hon. Lord Thurlow.

The SECRETARY (Mr. J. Owen Unwin) read the notice calling the meeting. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: I shall now proceed to make a few remarks as is customary on the report, but I am thankful to say that the occasion does not call for very many words from me. We appear before you again with what I think you must admit is a highly satisfactory balance-sheet, with one solitary exception, and that solitary exception, which is the key to the small dividend which we are able to declare, is the loss on exchange. That is a circumstance which is absolutely beyond the control of the Board. It has been unprecedentedly high, and of unprecedentedly long continuance, but we hope that in the future it will not occur again to the same extent. At the same time, this is so very serious a subject that I think you will pardon me for referring to it, as it absolutely absorbs on the present occasion 5 per cent. of the subscribed capital, so that instead of meeting you and being able to recommend a dividend at the rate of only 3 per cent., if it were not for this very unsatisfactory item, which shows a loss on exchange of £14,689, we should have had it in our power to offer you 8 per cent. in addition to the 3 per cent. already paid. This is a grievous state of things, and it behoves the Board to do what they can to make sure that this item does not recur—at any rate to the same extent—in succeeding years. Throughout the duration of last year our attention has been drawn to it, and we have always been hoping that the loss would be somewhat mitigated during that period, instead of which, as you all know, it has been constantly aggravated as time went on. It will be necessary for us to take steps to provide against its recurrence. Of course, there are two ways of meeting it, but neither of them should be attempted without very mature consideration. The one is the raising of the rates to subscribers, and the other is the adoption of a system of partial payments in gold and paper currency, because it is obvious that if we were paid half in gold and half in currency, the one would act as a counterpoise to the other. The matter, though ripe for consideration, cannot be decided hastily, and I am very glad to be able to say that we shall have the advice and experience of Mr. Fels, who has just returned from the River Plate, and who is in this room to-day. He arrived from Buenos Ayres the day before yesterday, but has not yet had time to give us the benefit of his views on this point. But you may take it for granted that we shall lose no time in consulting him and adopting whatever means we may think wise to mitigate at any rate this loss in future. There is another point I wish to draw attention to in connection with our dividend. We now give 3 per cent. in addition to the 3 per cent. which has been already paid, making 6 per cent. per annum, and I wish to say one word by way of comparison with the report we issued last year. Last year's report represented a period, as you know, of sixteen months, and for that period we paid 7 per cent. If you examine that carefully you will find that the 7 per cent. for 16 months is only 5¼ per cent. for 12 months, so that on the present occasion in offering you 6 per cent. for 12 months we are giving you ¾ per cent. more than for the corresponding period last year. Now, I must ask to say a few words upon our general business, which I am glad to say is in a highly satisfactory condition at the present moment. The Company commenced with 3,150 subscribers in Buenos Ayres. That figure has been raised by rather more than 50 per cent., which I think is extremely gratifying. In addition to that there is this feature, which I consider is no less satisfactory, namely, that there is an almost absolute cessation of complaints, and there is a general satisfaction expressed on the part of those we serve. That is a point to which we attach very great importance. We have supplied from the commencement a service of a very high standard of excellence, and much higher than people in Europe are accustomed to receive. I want to say one word about our sales business, which you may remember in the original prospectus was estimated to bring in a profit of £4,000 a year. That estimate has been more than doubled, which I regard as a satisfactory feature, and one that is likely to continue. As regards working expenses they have been unduly raised to a higher figure than they would have stood at by the occurrence some months ago of a very severe storm or cyclone. Although storms and hurricanes may be matters of frequent occurrence in the River Plate, still the one I refer to was of such unusual severity as to do very great damage to our system of wires, and from first to last it has caused an additional expenditure to us of something like £2,000 to repair the damage. Notwithstanding that, taking into consideration our increased number of subscribers, our working expenses do not stand at a higher figure than they did for the previous 12 months. I feel sure that you will be anxious to know a few details with regard to the Rosario business which we have acquired. Rosario is one of the most promising places from a commercial point of view: those who know it best anticipate for it a most prosperous future. There were two companies there, and we were exposed, as I think you know, until we purchased the second one, to great competition. Well, we entered into an agreement for the purchase of this opposition company, and I am thankful to say that the negotiations were carried out in an amicable spirit, and resulted in our obtaining the business at, I think, a very fair and reasonable price. We have now acquired the service of that company, and have installed in the united business at Rosario a very competent manager, who, I believe, is giving universal satisfaction. The number of subscribers has largely increased—not to 50 per cent., but, I should say, to something like 40 per cent.—during the past six months, and there is every prospect before us of a great improvement, so that instead of having anything to regret by the acquisition of the property, we may fairly congratulate the shareholders on the arrangement having been satisfactorily carried out. I believe that the acquisition of the property and the absolute control that it gives us over the telephonic arrangements of that rising town and the towns surrounding it and growing up along the line of railway between it and Buenos Ayres—along which, as time goes on, we shall undoubtedly lay a trunk line—I say that that circumstance has done more to consolidate our position and our power over the telephonic industry throughout the whole of the Argentine Republic than any other step that we could have taken. There is one satisfactory feature in the past year that I ought to allude to, and that is that, thanks to various circumstances, we have been enabled to get into the closest touch with our business on the other side of the world. This is greatly due to the presence here in the early part of the year of Mr. Krabbe, our consulting director at Buenos Ayres: he came over to England for a well-earned holiday in the latter part of last season and stayed with us for several months, attending our meetings and giving us the benefit of his experience. He has now returned to Buenos Ayres, where he has practically undertaken the supervision of our business—at any rate during the absence of our competent manager, Mr. Fels, who is here to-day. I am glad also to be able to tell you that two of your Directors have at different times during the year visited the River Plate—Mr. Coghlan and Mr. Le Rossignol. The former is unfortunately not able to be here to report on his visit, having been ordered abroad for the benefit of his health, but I am glad to say Mr. Le Rossignol is with us, and I hope he will address to you a few words explaining the satisfactory condition in which he found matters in Buenos Ayres when he left it but a few weeks ago. Thanks to all the circumstances to which I have referred, thanks to the energy displayed by Mr. Fels and by Mr. Krabbe in the management, and thanks to the successful acquisition of the business in Rosario, I believe that our present position leaves really nothing to desire except that the prosperity which we enjoy should continue. But I would ask you to believe that the business of this Company at the other side of the globe cannot be conducted from London by responsible directors without a considerable amount of ceaseless anxiety, and there are circumstances attached to telephonic business to which I venture to think the argument I venture to use is especially applicable. That anxiety, I am glad to say on the present occasion, has been greatly mitigated by two circumstances, one at home and the other abroad. These two circumstances—I hope I may be pardoned for saying so—have made this responsibility sit lightly, or more lightly on our shoulders than it would otherwise have done. One has been the knowledge that we have in our office in London a secretary and manager, Mr. Unwin, in whom we can not only place the utmost reliance for the due performance of the details of our business, but in whose wisdom and experience of South America we have the greatest confidence; and I have already referred to Mr. Krabbe and Mr. Fels for their assistance at Buenos Ayres. Without the feeling that we can rely absolutely on the gentlemen that assist us in this enterprise, I can assure you that it would be almost impossible to manage a business of this description and magnitude at the distance that London is from Buenos Ayres. The Chairman concluded by moving the adoption of the report and accounts for the last twelve months.

The DEPUTY-CHAIRMAN (Mr. J. Irving Courtenay) seconded the motion.

Mr. ALFRED LE ROSSIGNOL then gave a brief account of his recent visit to Buenos Ayres, where, he said, he found everything connected with the Company in a most satisfactory condition. The business had been very rapidly developed there, and was likely to still further increase, as might be inferred from the gradual increase to their list of subscribers. In the course of four or five years the town had advanced by 50 per cent. Buildings were being continually erected in the streets and squares, and the Company's prospects were very bright. The telephone was more in use there than in England, owing to the absence of good roads and to the faulty postal arrangements, Rosario he had not time to visit, but he believed that that town was developing more rapidly than Buenos Ayres; it was becoming the Chicago of the Republic.

Mr. THOMAS LLOYD, lately a director, then addressed the meeting, criticising the action of the Board with regard to the Rosario and Montevideo businesses.

Mr. J. T. LAWRENCE asked several questions respecting the accounts to which

Digitized by Google

The CHAIRMAN replied, while, in reference to Mr. Lloyd's remarks, he defended what the Board had done with regard to Rosario and Monte Video.

The resolution adopting the report and accounts was then put and carried unanimously.

The CHAIRMAN then proposed the re-election of Mr. Frank W. Jones, Mr. George Cooper and Mr. Alfred Le Rossignol as Directors.

Mr. LAWRENCE seconded the motion, which was agreed to *nem. con.*

On the motion of Mr. LAWRENCE, seconded by Mr. TURNER, the auditors, Messrs. Cooper Bros. and Company, were re-appointed.

Mr. DUNCAN then proposed a vote of thanks to the Chairman and Directors, whom he congratulated on their stroke of policy in securing the Rosario business.

Mr. KINGSBURY expressed his agreement with Mr. Duncan's views and seconded the motion, which was carried unanimously.

The CHAIRMAN having returned thanks, the proceedings terminated.

The Anglo-American Brush Electric Light Corporation (Limited).

An extraordinary general meeting of the shareholders of the Anglo-American Brush Electric Light Corporation (Limited) was held at the office of the Corporation, 112, Belvedere-road, Lambeth, on Wednesday last, the Right Hon. Lord Thurlow in the chair.

The SECRETARY (Mr. E. Garcke) having read the notice convening the meeting,

The CHAIRMAN said that in consequence of intervening holidays and other reasons it was found impossible to complete the formalities connected with the registration of the new company by the date of the present meeting, and as it was not advisable to confirm the resolutions passed at the previous extraordinary general meeting to wind up voluntarily the Corporation until the new company was registered, he had to move—

"*That the meeting be adjourned until the 14th of August, at the offices of the Corporation, at 3 o'clock p.m.*"

The DEPUTY-CHAIRMAN (Mr. R. P. Sellon) seconded the resolution.

A SHAREHOLDER raised the question whether it would not be in the interest of the body of shareholders to alter the place of meeting to the Cannon-street Hotel.

The DEPUTY-CHAIRMAN said it was merely a question of expense.

The CHAIRMAN said that they stood now in a position that they never occupied before. The whole industry was looking up—in fact, trade was reviving all round—and there was no reason why they should not derive some share of the general prosperity. But unless they had succeeded in forming an amalgamation of this description so as to put them on equal terms with the other manufacturing companies, they would inevitably have fallen into the background and ceased to occupy the prominent position with regard to electric lighting which they had always held. He had no objection, if he received a substantial number of requests on the part of shareholders, to hold the meeting on the following Wednesday at Cannon-street Hotel. As the Deputy-Chairman said, it was purely a matter of expense.

The resolution was then unanimously agreed to, and the proceedings terminated.

Aluminium Company (Limited).

The report of the Directors of this Company, which was submitted to the shareholders at the meeting at the Cannon-street Hotel on Wednesday, referred with regret to the results of the year's working, which had not answered the anticipations expressed by the Directors at the last meeting. After referring to some of the causes which had contributed to this state of affairs, the Directors attributed some of their trouble to the fact that aluminium bronzes are now made by electrical processes; and that although, as the Directors considered, these processes are much inferior to those manufactured by the Company, they are much cheaper, and are preferred by those who are making experiments with these alloys. The Directors have experienced difficulties in the process of manufacture, but they stated that these difficulties had been completely overcome.

At the meeting, Mr. GERALD W. BALFOUR, M.P., who presided, went largely into the question of the difficulties which had arisen in the manufacture by the Company of aluminium. They had been under the impression that the metal turned out by the Company would be pure enough to meet all commercial requirements, but had found that the French workers in the metal, who were the principal users of it at the present time, were not satisfied with its quality and preferred French manufacture to theirs, although they had to pay a higher price for it. He was happy to say that their difficulties had now been overcome by the discovery made by Mr. Castner for the purification of the chloride, which relieved them from all further trouble on this point. The invention was of extreme value to the Company, and had been patented. So great was the success attained by the new process that they could now make aluminium not only superior to the French, but with a purity of something like 1 per cent. over the metal made in France. The Chairman further alluded to the extreme competition in the aluminium market, which had seriously affected the Company's income, and had seriously disorganised the market. So far as the production of pure aluminium was concerned, the Company already stood in a position of advantage over all its rivals. With regard to the alloys, however, he did not think they were in so favourable a position. Alloys made by electrical processes were no doubt inferior to theirs—they were inconstant in quantity and were not to be depended upon, but they were cheaper than anything the Company could afford to sell. He could only hope that time, which was undoubtedly on their side, would give them the opportunity of ousting these inferior alloys. He referred to inventions which they had every reason to expect would result from experiments now being carried on at their works, and in particular he gave it as his opinion that the invention of Mr. Castner would not only lead to most successful results, but that the Company would shortly be in possession of a process which would place them above the fear of any competition, and that thereby they would be able to command the market for alloys as well as of the pure metal. He hoped that within a fortnight or three weeks they would know exactly how they stood with regard to these experiments, which were being carried on at Mr. Castner's expense, but which, if successful, would become the property of the Company on terms which had not been finally settled in detail, but which would make Mr. Castner's remuneration only dependent on the profits made. With regard to the financial position of the Company, he had every reason to hope for the best.

Sir HENRY E. ROSCOE, M.P., in the course of a few remarks, agreed with the Chairman that their difficulties had been extremely great, but through the skill and ability of Mr. Castner and the chemists on the spot, they had overcome them. They were in possession of new and valuable patents by which the metal could be prepared in a state of absolute purity, and they were now able to make it in any quantity.

The retiring Directors and auditors were re-elected, and a vote of thanks to the Chairman terminated the proceedings.

Keswick Electric Light Company (Limited).

On Thursday last week at the Court Buildings, the statutory and first ordinary meeting of the shareholders of this Company was held under the presidency of Mr. R. D. Marshall, of Castlerigg Manor.

Mr. JAMES FAWCUS (Messrs. Fawcus and Cowan, of Chester), the Managing Director and engineer, *pro tem.*, read the following report:—"I have much pleasure in giving you a report of the progress of your undertaking. The Directors have accepted the tender of Messrs. Johnson and Phillips, of Charlton, S.E., to supply all the necessary electrical machinery and instruments for the equipment of the central station at Forge, also to supply and lay down the mains and to provide a number of transformers for the conversion of the high tension current to a low tension at the consumers' houses. The dynamos and transformers will be Kapp's patent. Messrs. Johnson and Phillips, from the high position they occupy in the electrical world, may be depended upon to turn out thoroughly satisfactory work, and they are at present engaged on the construction of one of the large central stations now in progress in London. The large alternator will be driven by a turbine giving a high efficiency. This turbine is being supplied and erected by Mr. Frederic Nell, of London. The Directors consider that to guard against any temporary shortness of water owing to exceptional drought, frost, or other causes, it will be desirable to instal a steam engine and boiler as spare gear, which will be able to work the station in the event of any stoppage of water from these causes. They will accordingly, if possible, make arrangements to provide them. Plans have been prepared of the generating station and machinery in position, which are now before you. The contractors for the electrical and mechanical machinery have undertaken to have their work in running order by the 1st of October, and it is expected that the buildings will be ready for them by this time. Messrs. Johnson and Phillips are under contract to run the central station for a month after completion at their own expense, before handing it over to the Company, when it must be in thorough working order and to the entire satisfaction of the Company's engineer."

The election of the Board of Directors for the ensuing year resulted in the re-election of the Provisional Directors, Mr. R. D. Marshall, Mr. J. J. Spedding, Dr. Knight, and Mr. W. Wilson (Keswick Hotel), with the substitution of Mr. John Birkett for Mr. Fawcus, who was appointed engineer.

NEW COMPANIES REGISTERED.

D. HULETT AND CO. (LIMITED).—This company was registered on the 30th ult., with a capital of £35,000, in £5 shares, to carry on business as lamp manufacturers, brass and iron founders, mechanical, gas, hydraulic, and electrical engineers, and manufacturing chemists; also to take over, as a going concern, the business of D. Hulett and Co., of 55 and 56, High Holborn. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first; qualification, £500 in shares or stock; the company in general meeting will determine remuneration.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended August 2, 1889, amounted to £5,525, as compared with £5,601 last year.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of July, 1889, were £3,000, as compared with £3,086 in the corresponding month of last year. The receipts for the month of April, estimated at £4,000, realised £4,060.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of July, 1889, amounted to £1,677, as compared with £1,518 last year.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company for the month of July, 1889, amounted to £24,800. From the 1st January to 31st July, 1889, they were £154,200, against, in the corresponding months of 1888 and 1887, £156,000 and £150,520 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended August 2, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,916, as compared with £4,673 last year.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this company for the half-month ended July 31, 1889, amounted to £2,690, as compared with £2,857 last year.

ELECTRICAL AUTOMATIC DELIVERY BOX.—A petition by this company for the usual winding-up order came before Mr. Justice Kay on Saturday last, Mr. Marten, Q.C., appearing for the petitioner. He said the company was registered in January, 1888, when there was an agreement existing for the purchase of certain patents for £30,000—£10,000 in cash and the remainder in fully paid-up shares. The company did not commence business, because it was found that all the ground on which business could be profitably carried on was already occupied by other companies. On the appointment of a new board in January last negotiations were entered into with the vendor, and his purchase money was reduced from £30,000 to £7,150. The directors found, however, that there was only £1,000 in hand, and that it was perfectly useless to attempt to carry on business. The idea was that 2,000 machines should be erected, but they had only six, and they could not find any places where they could be profitably utilised. There were about £200 unpaid calls, and £1,700 uncalled capital; there were also the patents, which were of problematical value. Under these circumstances, the capital being inadequate, and there being no chance of carrying on business at a profit, the directors asked for the usual winding-up order. Mr. Renshaw, representing shareholders, supported the petition. Mr. Justice Kay made the order required.

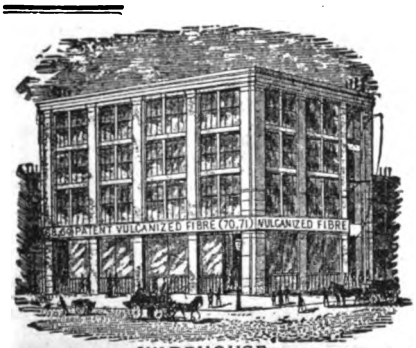
THE ELECTRIC APPARATUS COMPANY.—On Monday last a petition presented by the company to continue the voluntary winding-up under the supervision of the Court came before Mr. Justice North, in the Chancery Division of the High Court of Justice. Mr. Higgins, Q.C., who appeared for the company and two creditors, said the company was registered on February 23, 1884, its object being to carry on the business of wholesale and retail dealers in electrical apparatus. The nominal capital of the company was originally £12,000, but only £3,750 had been called up. The business of the company had recently become unprofitable, and in the month of July of this year, the company not being able, by reason of its liabilities, to continue business, at an extraordinary meeting, and upon due notice, a resolution was passed in the ordinary form that the company be wound up voluntarily, Mr. Friend, the secretary of the company, being appointed liquidator. The company was indebted to its bankers and sundry trade creditors in upwards of £1,500. It was expected that the assets, independently of the goodwill, would be enough to pay all the creditors. Mr. Cozens-Hardy, Q.C., who appeared for Mr. Montague, said he did not object to a supervision order, but submitted there ought to be a reference to Chambers to appoint an independent liquidator. After some discussion it was arranged that the voluntary winding-up should be continued upon the terms that if Mr. Montague's debt was not paid off within three months he was to have liberty to apply in Chambers for the appointment of a new liquidator, the company undertaking not to enter into any contract for realisation of the goodwill without giving Mr. Montague seven days' notice.

RAILWAY ELECTRICAL CONTRACTORS (LIMITED).—Mr. F. E. Hersee, of 144, Leadenhall-street, E.C., has been appointed liquidator of this company.

SCHMIDT DOUGLAS ELECTRIC COMPANY.—Two petitions to wind up this Company came before Mr. Justice Chitty, in the Chancery Division of the High Court of Justice, on Saturday last. The petitions were presented by creditors in respect of goods sold and delivered. The company admitted the debts, and that it was not able to pay. Counsel asked that one order might be made on both petitions, as the second one was presented without knowledge of the first. His Lordship made one order on the two petitions.

DISSOLUTION OF PARTNERSHIP.—It is announced that Messrs. E. H. Harling and C. B. Aird, trading as electricians under the name of Messrs. Harling, Aird and Co., of 7, Railway-approach, London Bridge, S.E., have dissolved partnership.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

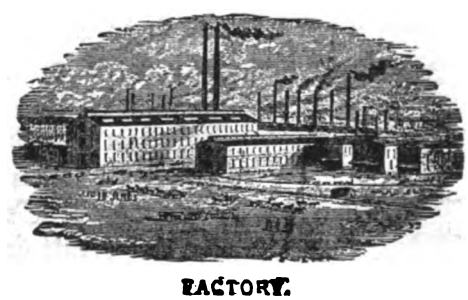
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

JABLOCHKOFF'S
DISTRIDUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Johnson & Phillips.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

MANVILLE & MADGEN, *Managing Directors.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 587.—Vol. XXIII. FRIDAY, AUGUST 16, 1889. Price Fourpence.

NOTES.

Yesterday afternoon the Electric Lighting Provisional Order Bills were read a third time in the House of Lords and passed. Lord Crawford, in the concluding discussion, stated that although much pains had been taken in framing these Orders, the testing and meter clauses were unworkable—an opinion which we ventured to express at the time the Model Order was published.

The summary extinction which the Westminster Syndicate has suffered at the hands of the Select Committee of the House of Lords cannot but remove any lingering doubt which may exist as to the importance of the local inquiries held under the Electric Lighting Acts of 1882 and 1888. Had the Westminster Syndicate taken Major Marindin's inquiry a little more seriously, and put in an appearance there as "persons locally interested," the fact that they had spent a large sum of money on machinery, and were actively engaged in electrical distribution would, we feel sure, have had considerable weight with the Inspector, especially if, as their counsel implied, they had only been prevented from applying for a Provisional Order by reason of their being registered eleven days too late. As it was, the Syndicate choose to allow the Westminster Electric Supply Corporation to fight its way to the House of Lords before entering into the field against them, and the Committee, very properly we think, held such belated opposition to be unreasonable.

In spite of the pathetic and by no means unnatural appeal of the St. James's and Pall Mall Company to be granted at least two years' peace and quiet in the area covered by their license, the Select Committee decided to allow the London Electric Supply Corporation to maintain their existing foothold in the district. This decision is noteworthy as demonstrating that the Legislature, as well as the Board of Trade, is no believer in the efficacy of "potential competition," but intends to carry out Major Marindin's suggestion of bringing, wherever possible, two companies using different systems of distribution into immediate competition.

We recently indited an article on "Alternate-Current Working," which, although by no means intended to be controversial in character, drew from Mr. Swinburne (*see* our last issue) a rejoinder, in which he maintains that the "old theory of synchronism" stands in need of no modification whatever. For our part we have not the least desire to impeach Dr. Hopkinson's mathematics, but we still venture to believe that the conditions of the problem are, to say the least, not fully expressed in the formula he has given us. Dr. Hopkinson can easily afford to be less than infallible. Mr. Swinburne apparently thinks that he cannot.

If Mr. Swinburne be justified in his assertion that the old theory is not only "perfectly clear," but is also competent to explain all that needs explanation, how comes it to pass we may fairly ask that this same theory, as interpreted by Mr. Swinburne himself, pointed not long ago to conclusions some of which we now know to be hopelessly at variance with the facts? To particularise only some few instances out of several at hand, did or did not Mr. Swinburne (*circa* 1887-9) draw the following deductions from the theory in question?:—

1. That coreless armatures would only run parallel with no load. (*Journal* Institute Electrical Engineers, XVII., 401.)
2. That with such armatures it would be necessary to make up for the lack of self-induction by putting iron elsewhere in the circuit. (*Journal* Institute Electrical Engineers, XVII., 401.)
3. Did he not lay great stress, so recently as March last, on a device of his own which was to solve the problem by the application of an "induction-coupler?" (*Journal* Institute of Electrical Engineers, XVII., p. 401; XVIII., p. 221.)
4. That with a parallel constant E.M.F. system of supply the use of such synchronising motors was incompatible with efficiency. ("Practical Electrical Measurement," p. 152.)
5. That such motors would not work well with varying load. ("Practical Electrical Measurement," p. 152).

Would it not be as well if Mr. Swinburne would now explain which, and how many, of these assertions he still holds by? For our part we are prepared to traverse them all.

So much for the *argumentum ad hominem*. Let us now consider briefly the essence of the controversy, which, we take it, turns upon the question whether or not Dr. Hopkinson's formula of 1884 expresses fully the necessary and sufficient condition for the parallel working of alternators. This, we need scarcely remind our readers, amounts to saying that the time-constant

Digitized by Google

L/R must bear a certain fixed ratio to the periodic time of the current. Now in Mr. MORDEY'S Paper he stated that *he thought* his machines would synchronise equally well at any periodicity, and we happen to know that this has since been confirmed by experiment. This is a most important point. Unless Mr. SWINBURNE is prepared to show that in this machine the value of L (which our correspondent is fond of assuring us is a variable) varies inversely with the speed, we are at a loss to imagine how he can possibly continue to maintain his present views. On another main issue, that of the nature and extent of the *rôle* attributed to self-induction, and apart from its relation to the periodic time, Mr. SWINBURNE has also to explain how it comes to pass that whilst the actual behaviour of the machine is entirely dependent upon the value of the impressed field, the value of the self-induction coefficient is scarcely affected by any variation which the field may be caused to undergo. He will probably allow that when there is no impressed field synchronism is impossible. Yet even in this case L has been shown to be nearly unchanged. Here, then, is another problem waiting for Mr. SWINBURNE'S elucidation in terms of the old theory. It seems to us that on these points Mr. MORDEY'S views were quite clearly set forth in his recent paper and reply. But Mr. SWINBURNE concludes his letter somewhat illogically by remarking that he really does not understand what Mr. MORDEY'S opinions are. We venture to recommend our correspondent to make a further effort to master this side of the argument before he continues his attempts to upset it.

BEFORE leaving the subject, we have just one word to say upon Mr. SWINBURNE'S controversial style. Epigrammatic and facile as it undoubtedly is, we think he would do well to sacrifice some of its superficial brilliancy in order to obviate a certain air of precocious omniscience with which his utterances are somewhat painfully pervaded. For so young a man the extent of Mr. SWINBURNE'S practical and theoretical knowledge of physical science does him infinite credit, but he really has no sufficient title to deliver his views with all that tone of contemptuous infallibility which, in his weaker moments, he so much affects. "People," Mr. SWINBURNE tell us, "have been hopelessly confused by one of Mr. MORDEY'S experiments, and most of the conclusions drawn from it must be reversed to have any meaning." We shall not trouble ourselves to contest this assertion, but we do seriously think that when Sir WM. THOMSON and Mr. KAPP are the only "people" who so far have publicly drawn any conclusions from the experiment in question, Mr. SWINBURNE (if only out of consideration for their maturer years) should try to be more gentle in his mode of controverting their opinions. It will be seen from what we have said that our difference with Mr. SWINBURNE is not so much in respect of his present interpretation of the Mordey experiments, but in what we consider to be his unjustifiable assumption that he has known all there was to be known, at least since 1887, and that there is nothing new to be learnt from recent investigations. In the unpopular days of science the customary series of assertions with which new discoveries were greeted was, first, it is not true; second, it is not new; third, we knew all about it years ago. We are sorry to see Mr. SWINBURNE posing in this ungraceful and antiquated attitude.

WE are gratified to notice that an attempt is being made during the present naval manœuvres to remedy a glaring defect in the programme of previous operations. Last year we drew attention to the manifest disadvantage at which the defenders were placed in consequence of there being no adequate means of communication between the signalling stations on land and the friendly fleet off the shores; and we pointed out how easily the much-needed system of signalling might be established. We do not know whether our suggestion has been acted upon, but we happen to know that one of several naval signalling officers who have in the interval been trained in Morse telegraphy is now on board H.M.S. "Hercules"; and it is from this vessel that the experiment, reported in Monday's *Standard*, of signalling by flash of lamp, in Morse code, to Prawle Point, was successfully accomplished. About midnight, at two miles distance, the "Hercules" flashed the messages by dots and dashes, "Machinery working very satisfactorily. Report to Lizard."

SIGNALLING from ship to shore is, however, of little use, unless the message can be forwarded on to the neighbouring naval and military stations, a fact which was brought to light on more than one occasion with painful emphasis during the last naval manœuvres. Thanks to Admiral TRYON, who subsequently reported on this matter, the authorities have organised a system which during the present operations will, according to the *Standard's* correspondent, enable every signal station on the coast to give prompt information to the military and naval depôts in its district of the movements of any hostile fleet approaching our shores. As permission has this year been given to call out the regular and volunteer forces in the threatened localities, it is probable that the Royal Engineers have been at work connecting the coast stations with the main land lines. From a notification in this week's "Post Office Circular" it would appear that 28 coastguard stations have been connected telegraphically with their nearest postal telegraph offices. Much to our surprise, the full list of these places is given—and will be no doubt promptly communicated to Admiral BAIRD'S attacking fleet!

WE report in another column some interesting and important information as to the actual cost of working the Brussels electric tramways with Julien accumulators, as given by M. MICHELET, the Director of the Tramway Company, the figures being based on two years' experience. The cost of working the same lines with horses is estimated at 25 centimes per car-kilometre, and the cost of the electrical system, *exclusive* of the maintenance of stationary machinery, royalties to the inventors, interest upon the capital, and depreciation of plant, but including the cost of maintaining the accumulators, comes out at the same figure. But as the horse-car estimate includes stud renewals, electrical working shows a serious loss. It must, however, be remembered that the Brussels lines are not only run over steep gradients, but are also badly laid, so that the batteries were

Digitized by Google

tested somewhat severely. We have never yet been convinced that accumulator traction can be economically worked except when the conditions of the service are of a favourable character. We shall, however, be interested to hear further reports from America, where, so far, the Julien system appears to have done much better.

THE subjoined information is taken from an electrical journal which appears weekly in one of the Western States of America. We have no doubt that our readers will feel thankful for its preservation :—

The "ohm" is named after a Professor Ohm who invented it as a standard or unit of measuring the resistance to an electric current in its transmission through a body, usually a wire. A volt is the standard or unit of electromotive force. European electricians call it an "element." It is the parts of which an electric battery is constructed, and consists of plates of zinc, copper, or prepared carbon, which are immersed in a liquid. A battery consists of a number of volts, the number varying with the strength of the electric current to be generated. The term "volt" is formed from the same as Volta, the Italian scientist whose name is prominently connected with the development of electric science.

Interruption of the New Zealand Cable.—We are officially informed that telegraphic communication with New Zealand is interrupted.

Kilmarnock.—At the monthly meeting of the Kilmarnock Town Council last week it was agreed to oppose the application of the Scottish House-to-House Electricity Company.

Teignmouth.—The Teignmouth Local Board have decided to send a reply to the Devon and Cornwall Electricity Supply Company to the effect that they oppose their application.

Bangor.—Notice has been received from the Midland House-to-House Electricity Company of their intention of applying for a Provisional Order to enable them to supply Bangor with the electric light.

Berlin.—A fire broke out recently in the electrical section of the Machinery Hall in the Exhibition of Apparatus for the Prevention of Accidents. The central division of the section was destroyed, but the fire was prevented from spreading.

Telegraphic Communication with Obock.—It is officially announced that telegraphic communication has been established with Obock on the Red Sea, the cable having been laid by the Eastern Telegraph Company's cable steamer "Chiltern."

The Edison Patent in Canada.—Our readers will probably remember that a decision was recently given in the Canadian Courts upsetting the Edison lamp patent. This decision has now been set aside by the Superior Court and the case will be re-tried.

Paddington Vestry.—At a meeting of this vestry last week the Clerk reported that a valuable report on the question of the electric lighting of the district was being framed by the committee appointed for that purpose, and that it would be ready for presentation after the recess.

The Birmingham Exhibition.—A fire occurred at the Electrical and Industrial Exhibition last week, the prompt extinction of which was due to the efficient action of the electric fire-alarms, which have been erected in the hall in connection with the exhibits of Mr. Julius Sax.

Folkestone.—The Corporation on Thursday last week fixed the official seal to the contract of Messrs. Crompton and Co. No less than five companies have intimated their intention to the Town Council to apply to Parliament for powers to supply the electric light to private consumers in the town.

Warrington.—At the meeting of the Warrington Town Council last week it was reported by the Gas Committee that they had instructed the Town Clerk to oppose the applications, of which notice had been given by three electric light companies, for power to supply the borough with the electric light.

Lynton.—The Lynton Local Board have decided to accept Mr. Green's terms for lighting Lynton, Lynmouth, and the main road between the two places by electricity. The Valley of Rocks, Lyndale, Torr's Park, and Crown Hotels, and several shops and private residences, are also to be lit with the electric light.

The Post Office Magazine.—*Blackfriars* is this month a capital number, most of the articles being entertaining and well written, the one by Mr. H. Badcock, relating some curious correspondence of savings' bank depositors with the Post Office, being especially noticeable for its lively humour and grace of style.

Overhead Wires.—On Thursday last, in answer to Sir G. Campbell, Mr. Ritchie said that in some cases local Acts have been passed which empower the authorities to make by-laws on the subject of overhead wires. With the exception of these cases local authorities are not enabled to make by-laws on the subject.

Sheffield.—In reply to the notice of the Electric Construction and Maintenance Company, the Improvement Committee of the borough have recommended the Council not to give consent to the granting of a Provisional Order, on the ground that the Council may probably themselves seek to obtain powers necessary for the purpose.

Peterborough.—Two companies have served notices on the Corporation of their intention to apply for Provisional Orders to supply Peterborough with electricity. The Corporation, however, have refused their sanction, and have instructed the surveyor to prepare a scheme for the supply of electricity by the Corporation within the borough.

Ayr.—The Ayr Town Council intend to apply for a Provisional Order to enable them to light the streets and town buildings by electricity. The water of the dam at Ayr mills will, it is thought, be sufficient to supply the motive-power for the dynamos. A report will be submitted by the Council before any steps are taken in the matter.

Dublin.—At the meeting of the Dublin Corporation on Monday last, the report of the special committee recommending that application be made for sanction to the borrowing of £50,000 to carry the electric lighting scheme into effect, and also that the committee be empowered to acquire a site other than Island Bridge, was read a first time.

St. Helen's.—At the last quarterly meeting of the Town Council, notice having been given by two companies that they intended to apply to Parliament for a Provisional Order authorising the supply of electricity within the borough, the Gas and Lighting Committee recommended the Council to apply for a Provisional Order to enable them to supply electricity for public and private purposes in the borough. This was agreed to.

Holborn Board of Works.—At the meeting of this Board, on Monday, the Committee of Works recommended that the Board consent to a license being granted to the Gwynne-Pilsen Company to supply electricity in the Holborn District, subject to the company obtaining an Order from the Board of Trade similar to the Order granted to the Metropolitan Electric Supply Company in regard to the district. The report was adopted.

Gent and Co.'s Catalogue.—This catalogue is mainly devoted to electric bells and similar apparatus, and contains concise instructions as to running and testing wires and setting up batteries. The illustrated list of bells, pushes, and electrical alarms is very complete, and a large number of pages is also allotted to electro-medical and surgical apparatus. We notice, amongst other things on this list, a useful pole indicator and Hick's glass bead hydrometer.

Lincoln.—A monthly meeting of the Lincoln Urban Sanitary Authority was held on Tuesday last week. The Lighting Committee reported that they had received a notice from the Midland House-to-House Electricity Company and the Electric Construction Company of their intention to apply for powers to supply electricity to the city. The Committee recommended the Council to oppose the schemes. The Council confirmed the action of the Committee.

Digitized by Google

John Fowler and Co.—The revised catalogue issued by John Fowler and Co., of Leeds, numbers some 70 pages, and contains an exhaustive list of engines adapted to electric lighting and other purposes. We are glad to notice that this firm have given up the use of the misleading term nominal horse-power, and now designate the different sizes by letters specifying the actual power the engines give off at the pressure and speed mentioned in the price list.

Fenton.—At the last meeting of the Fenton Local Board, the Clerk reported that he had received notices of intended applications for Provisional Orders from the Municipal Electric Light and Power Corporation and the Midland House-to-House Electricity Company. It was considered that the interests of the Board would be affected by such a course, and the Clerk was instructed to take the necessary steps to place the Board in a position to oppose the application.

Exports of Electrical Apparatus.—The following table, taken from the Board of Trade returns, shows the values of the exports of telegraphic wires and apparatus connected therewith during July and the first seven months of the year, in comparison with the corresponding figures for the previous two years :—

	1889.	1888.	1887.
Month of July ...	£32,909	£21,571	£195,950
Jan. 1 to July 31..	609,365	265,784	384,762

Dundee.—On Wednesday last week, at a meeting of the Dundee Gas Commissioners, the Committee on Electric Lighting recommended the Board to apply for a Provisional Order, and also to intimate to the parties concerned that the Commissioners would oppose any similar applications by speculative companies. The recommendation was approved of, and a Committee was appointed for the purpose of gathering information in regard to the electric light.

Severe Thunderstorms.—On Wednesday, last week, a farm servant at work in an open field near Driffield was struck by lightning and killed. On Sunday last the Midlands and the North were again visited by destructive storms. At Birmingham considerable damage was done to property, but no fatal accident occurred. At Nottingham the Roman Catholic Chapel was struck by lightning, and the bell turret was damaged. At York, on the same day, several individuals were injured, and some houses were partially wrecked by lightning.

Arc Light Photometry.—The question of the actual candle-power of the lamps in the Unter den Linden lighting having been raised, Prof. Slaby was requested to go fully into the matter, and his results with numerous curves for candle-power in various directions are given in a lengthy Paper in the *Verhandlung des Vereins zur Beförderung des Gewerbfleisses*, No. 4, 1889, which will well repay perusal by those interested. An abstract at some length is given in the *Electrotechnische Zeitschrift*, No. 13, 1889.

Halifax.—At the last meeting of the Electric Lighting Committee of the Halifax Town Council, the Town Clerk submitted notices from the Electric Construction and Maintenance Company and the Yorkshire House-to-House Electricity Company of their intention to apply for Provisional Orders. The Town Clerk was instructed to inform the companies that as there were already two companies supplying electric light with the permission of the Corporation, any application for Provisional Orders by the above-named companies would be opposed.

Bradford.—At the meeting of the Bradford Town Council, on Tuesday last, Alderman F. Priestman, in moving the adoption of the proceedings of the Gas and Electricity Supply Committee, said that the arrangements for the installation of the electric light were now practically complete, and within the next week probably the members of the committee would have an opportunity of witnessing a test of the installation. The installation would be handed over to Messrs. Siemens for six weeks in accordance with the terms of their contract, after which the Corporation would take the matter into their own hands. After September 1st the contracts for the supply of the electric light would come into force.

The Tabor Indicator.—We have received from Messrs. J. Musgrave and Sons, of Bolton, an excellent little handbook relating to the Tabor Indicator, and containing a number of tables which should prove of great use to those connected with steam engines. The chief feature of the Tabor Indicator is the method employed to give a straight line motion to the pencil, a stationary plate containing a slot, the curve of which just compensates the tendency of the pencil point to move in a circular arc, being used to guide the motion of the pencil bar.

Leith.—The report of the General Committee of the Leith Town Council upon the notices received from the Brush Company, the Electric Construction and Maintenance Company, the Scottish Electric Supply Company, and the Scottish House-to-House Electricity Company, was read at the last meeting of the Corporation and approved of. It was to the effect that the Council should decline to give its consent to the intended applications, and that it should act in conjunction with the Edinburgh Town Council or Gas Commission to oppose such application.

The Edinburgh Exhibition.—At the last meeting of the Executive Committee of the forthcoming Exhibition, it was unanimously agreed to fix the title of the Exhibition thus :—"The International Exhibition of Electrical Engineering, General Inventions, and Industries, Edinburgh, 1890." The guarantee fund was reported to have already reached £5,000. It was arranged to send a deputation to London to endeavour to see Mr. Edison this week to make definite arrangements as to his exhibits. The site at Merchiston, consisting of about 40 acres, has been definitely settled upon.

Arbroath.—At a meeting of the Committee of Management of the Gas Corporation on Friday last, a letter was read from the Scottish House-to-House Electricity Company, giving notice that they intended to apply for a Provisional Order, and asking the consent of the Gas Corporation to their application. It was unanimously agreed to recommend to the Police Commission and Gas Corporation not to give their consent to the application, and to forward a request to the Board of Trade for time to consider the needs of the community in respect to lighting, and the desirability of the Board applying themselves for a Provisional Order.

Plymouth.—The result of the canvass of Mr. Bingham, engineer of the Devon and Cornwall Electricity Supply Company, is that over three thousand incandescent lights have been definitely ordered for various shops, private establishments, and public places. The number of applications received being so satisfactory, arrangements are being made to proceed with the work without delay. The plant to be laid down in the first instance will be sufficient to supply 4,000 incandescent lights and 1,000 arcs, and when this has been ordered no further engagements will be entered into until additional plant is introduced.

Torsion in Silk Fibres.—The Munich Institute of Physical Research has published some figures comparing the torsion of a silk fibre with that of a platinum wire ·004 millimetre (0·16 mils). The breaking strain of the wire was 97 grammes, that of the silk fibre 36 grammes. The torsion was determined by suspending a small magnet with a mirror in the earth's field, first by the wire and then by the fibre, the upper end being fastened to a torsion head, which was turned round until a given deflection was produced on the scale. The results obtained show that the silk fibre is about 200 times better than the platinum wire.

Derby.—At the meeting of the Derby Town Council on Wednesday last week the Parliamentary Committee reported that they had considered the question of lighting the town with electricity. They did not consider that a scheme for the lighting of the whole town by this means would at present be prudent, but, at the same time, they were of opinion that a modified scheme for public and private purposes was highly desirable, and that the time had arrived when the Corporation should move in the matter. They therefore recommended that authority should be given to them to make the necessary application to Parliament.

Safety Insulating Staples.—The old-fashioned iron staple hammered in tight against electric light and bell wires, cutting the insulation and frequently fracturing the conductor itself, has long been an abomination in the eyes of those who like to

Digitized by Google

see good work in every detail of an installation. The "safety insulating staple," made of specially-prepared insulating material, which is being introduced into this country by Messrs. Mosses and Mitchell, of Chiswell-street, is therefore likely to have a wide sale if it can in any way compete in price with the old article. We may mention that these insulating staples are the only ones used on board the ships of the United States Navy.

The Edison Lamp Patents: Important Decision.—The National Company for the Distribution of Electricity by Secondary Generators writes us as follows:—"We have just received the following cablegram from Mr. George Westinghouse, junior, of Pittsburgh, U.S.A., the contents of which may interest your readers:—'Decision yesterday, Judge Wallace, in United States Court, in case conducted by Edison Company, construing Supreme Court decision, holds American patent expires with prior patent abroad, even when void for failure to work or pay taxes. This decision overthrows high-resistance carbon filament patent, main reliance of Edison Company for maintaining monopoly incandescent lighting in United States.'"

Davey, Paxman & Co.—We have received from Messrs. Davey, Paxman and Co., of Colchester, a copy of the revised edition of their well-known catalogue. The publication, which is admirably illustrated throughout, contains full details with regard to the numerous types of engines and boilers manufactured by this firm, including portable and semi-portable, vertical and horizontal, high-pressure and compound engines, and Cornish, Lancashire, multitubular, "Essex" vertical, and "Economic" safety boilers. The catalogue also contains illustrations of Davey, Paxman and Co.'s electric light shed at the Colonial Exhibition and of their fine plant at the air-compressing station in the Rue de St. Fargeau, Paris. The information given in this publication is of a very complete character, and it should be of great value to all those who wish to purchase high-class engines and boilers.

Orleansville (Algeria).—The contract for the erection of a central-lighting station at Orleansville, to which we referred some time back, was obtained by MM. Gally and Daloz, and the installation is expected to be in working order within the next few weeks. Six kilometres outside the town there is an hydraulic station comprising a 70 horse-power turbine and two 35-ampere 500-volt dynamos connected in series. The central station in the town will contain a Babcock and Wilcox boiler, a Weyher and Richemond engine, a Desroziers-Bréguet dynamo giving 110 volts and 250 amperes, and 350 accumulators of the Planté type. In the daytime the accumulators will be charged in series by the dynamos at the hydraulic station, and discharged in parallel at night. The steam plant is intended to serve as a stand-by in case the water should fail. The town lighting will require 250 16 candle-power lamps, which are to be hung in the middle of the streets in groups of three; the plant is capable of supplying 600 lamps. Overhead bare copper wires are used throughout.

An Electric Reading Lamp on the Automatic Principle.—Passengers by the main line of the South-Eastern Railway will henceforth have the benefit of an electric reading lamp, with which the company's carriages are being equipped. The apparatus is contained in a small box, five inches by three, which is placed immediately under the rack, and over the passenger's head. By the introduction of a penny at the top of the box, and the subsequent pressure of a knob, a five-candle power light is obtained, which will burn for half an hour and then extinguish itself automatically. The light may be continued for an indefinite period by the renewed insertion of a penny every half hour. A special feature of the invention is, we are glad to learn, that if the apparatus should happen to be out of order, the penny will drop right through and deposit itself in such a way at the bottom of the box that it may be recovered, the same result being obtained if a half-penny or other coin not of the size of a penny be inserted. One accumulator to every carriage supplies the current to the whole number of lamps in each compartment.

Manchester.—At a special meeting of the Manchester City Council on Wednesday last week the question of an application by the Corporation for a Provisional Order came up for discussion. Alderman Lamb, chairman of the Gas Committee, in moving that a Provisional Order be applied for, said the Gas Committee were not in opposition to the electric light or any other invention that could be shown to be for the public good. Alderman Sir J. Harwood regretted that there was not a more encouraging past to go upon, and said that the position of the Corporation, if it obtained powers, was a very serious one, inasmuch as every person residing within the zone applied for could compel the Corporation to supply them within three years. He was sorry the application could not be deferred. Alderman Asquith pointed out that unless the Corporation took action, the half-dozen companies already in the field would get powers and supply the light. The Mayor said the risk incurred was not immediate. They had three years to turn round in, and they could defer it for some time at all events. They were not obliged to at once commit themselves. The resolution was then put and carried unanimously.

The Waring and Tatham Underground Cables.—We have received from Mr. Richard Waring, of Queen-street, a pamphlet containing a description of the Waring Underground Cable system and numerous testimonials from various users in the United States. These lead-covered cables, which were fully described in *The Electrician* of November 2, 1888, are favourably known for their durability and high insulation under trying conditions. In the lighting of the Hoosac Tunnel (Mass.), for instance, Waring cables were finally adopted after several kinds of special insulation had succumbed to the excessive moisture and sulphureous fumes. The Fowler-Waring Cables Company (Limited) has now been formed to undertake the manufacture in this country both of this type of cable and of Tatham's lead-covered cables, which are in use on the City and Southwark Subway, and which are at present supplied by the well-known engineering firm of Fowler and Co. (Limited), of Leeds. Under the present rearrangement, and in view of the immense prospective requirements for underground cable work in this country, we can only anticipate a prosperous future for the new company. We understand that the share capital was already more than covered on Wednesday last. The lists close this day (Friday) at noon. A full prospectus of the new venture will be found in our advertising columns.

The Paris Meeting of the Institution of Electrical Engineers.—The following circular, giving an outline programme of the arrangements for this meeting, has been issued to those members who have signified their intention of attending:—On Friday evening, August 23rd, a joint meeting of the Institution and the Société Internationale des Electriciens will take place at the rooms of the Société, 44, Rue de Rennes (Place St. Germain des Près), at half-past eight, when the members will be received by Colonel Sebert, President of the Société, who will inaugurate the proceedings by delivering a short address of welcome. This will be followed by addresses from Sir William Thomson as President of the Institution, and Monsieur Mascart, President of the Paris International Electrical Congress, 1889. Various instruments and apparatus will be exhibited, including Carpentier's "Melophone," Edison's "Improved Phonographs and Telephones in communication with the Opéra," &c. A lecture will be delivered, at a date to be fixed hereafter, at the Central Electrical Laboratory, by Prof. Joubert, on "Hertz's Recent Investigations," when most of his experiments will be reproduced. M. Abdank-Abakanowicz will lecture, with full experimental illustrations, on Elihu Thomson's latest Electrical Investigations, including his Electric Welding process. On subsequent days, which it is not desirable to fix until the Congress at their first meeting (August 24th) have settled the days and times for *their* meetings, the following works of interest will be visited:—Messrs. Sauttier Lemonnier's Works; Messrs. Menier's Cable Works; the Telephone Society's Construction Works; the Central Electrical Laboratory; the Central Electric Lighting Stations at the Palais Royal, the Rue Druot, the Grand Opéra, and the Eiffel Tower. We learn that members, associates, and students of the Institution of Electrical Engineers to the number of 123 have announced their intention of taking part in the Paris meeting of the Institution. If anything like this number actually attend, the meeting ought to prove a decided success.

M. LEBLANC ON ALTERNATING MOTORS

(*Continued from page 346.*)

M. Leblanc continues at great length in *La Lumière Electrique* his Paper on Alternating Motors. In the later chapters much space is occupied with mathematical investigations, whose positive value is not, perhaps, very great, since the actual conditions of the problem are not very closely represented by the formula employed. Our author's speculations are, nevertheless, frequently ingenious and suggestive, even when they are not wholly novel, nor at present practicable. What here follows must be taken rather as an informal *résumé*, interspersed with some comments of our own, than as a cut-and-dried abstract of the original. M. Leblanc, we may add, is not easily abstracted, because he wanders up and down in his subject in a somewhat promiscuous manner.

On leaving the Mordey "commutating" motor (to which, however, he again returns) the author enters upon an "Investigation of the means of avoiding the apparent increase of resistance due to the phenomena of self-induction in circuits traversed by an alternating current."

He mentions three principal methods—

1. If in two branches of the same circuit having coefficients of self-induction L and L', the current has the values I and I' respectively, we may endeavour so to arrange matters that the sum

$$L I^2 + L' I'^2$$

shall maintain a constant value.

2. A second circuit (or a branch circuit) may be caused to react upon that in which we wish to reduce the impedance, in such a manner that the electrical inertia of the joint system is very small, approximating to zero.

3. We may intercalate a condenser of such proportions that the sum of the potential energy due to the inertia of the circuit ($\frac{1}{2} L I^2$) and of the potential energy stored in the condenser ($\frac{1}{2} K P^2$) may be constant.

M. Leblanc next considers how far these several methods are capable of practical realisation. (1.) If we knew how to employ oscillatory currents of short period (say, 4×10^6 oscillations per second, such as Hertz and Lodge are familiar with), the first method could readily be tried. The wave length of such oscillations would be about 1 metre, and it would merely be necessary to provide two identical sets of apparatus in which the active part of the circuit A is displaced one-quarter wave length in respect of the circuit A'. Then, at any instant t, the current in A may be represented by

$$I = J \sin 2\pi \frac{t}{T},$$

where J is a constant, and at the same moment in circuit A' the current is

$$I' = J \cos 2\pi \frac{t}{T}.$$

It follows that the potential energy of the system A A', if L be the self-induction of each circuit, is given by

$$L (I^2 + I'^2) = LJ^2 \left(\sin^2 \frac{2\pi t}{T} + \cos^2 \frac{2\pi t}{T} \right) = L J^2,$$

which is a constant (if L be constant).

"It will, therefore, be possible," says M. Leblanc, "to suppress the increase of resistance due to self-induction by employing currents of very high period." We must confess that in the light of our present knowledge this idea seems to us to be hopelessly chimerical; even if the practical difficulties of generating such rapid current waves in an available form were overcome the author still overlooks the fact that the peripheral distribution of currents of one metre wave length in the cross-section of the conductor would cause an increase of resistance which would probably be fatal. M. Leblanc does, however, recognise that his idea is not immediately available, and he is content to claim credit for priority of the conception.

(2.) The author attacks the second method by means of a mathematical investigation covering many columns of type, the upshot of which is that the condition to be aimed at is expressed in the following equation:—

$$T^2 R R' + 4\pi^2 (M^2 - L L') = 0,$$

where R R' may be the resistance of the armature and field magnets respectively, L and L' their coefficients of self-induction, and M the coefficient of mutual induction. Now, if the period T be small the first term may easily become negligible; we have then to make $M = \sqrt{L L'}$. This is, of course, equivalent to the condition that the armature and the field-coils shall possess the same magnetic circuit, in which, moreover, there is to be no leakage. It is easily seen that this condition is unattainable in a motor where the presence of a moving part necessitates an air-gap, though in a transformer it is very nearly realised. It is also evident that in practice the value of M will, as a rule, vary with the displacement of the armature. M. Leblanc shows, however, that the more nearly $M = L = L'$ the more nearly will the work done under an E.M.F. of given mean value approximate to the value of the work done in the same circuit by the equivalent continuous E.M.F., and he also shows that the internal work lost in the armature is the same in each case. M. Leblanc is here, however, tacitly assuming that L and L' are constant for all values of the current, and that M is of the same value for all positions of the armature—neither of which is strictly true; but we shall see how he proposes to circumvent these difficulties. As to the possibility of realising this ideal M. Leblanc proceeds as follows:—"Let us suppose that the armature (*circuit mobile*) is composed of a large number of similar coils, connected in the usual way with a Gramme commutator.* Let us arrange a pair of brushes to bear upon the commutator at two points so chosen that the closed circuit thus formed shall have a coefficient of self-induction equal to that of the field coils (*circuit fixe*), so as to satisfy the above relation. If we displace the armature by an amount corresponding to the interval between two commutator bars it furnishes an element of work, ΔW, which has been evaluated above.† But immediately, by the action of the commutator, the initial state of things has been restored (M has returned to the value M_1), and this without the expenditure of energy. The same operation being repeated indefinitely it will be seen that the machine will behave very nearly as if the current were continuous."

M. Leblanc then describes in outline a machine in which he hoped actually to embody these principles. It may be roughly described as a Siemens' alternator, with iron in the cores of the bobbins, and with the depth of the coils considerably extended in the direction of the pole-pieces. There are only six coils in the armature, and the commutator bars are separated by insulation of equal width. A single pair of brushes is made to bear upon the commutator in the usual way, but instead of being joined up to the external circuit they are directly connected together. The main current traverses the field-magnet circuit alone, and in this respect the motor resembles the Tesla and the Elihu Thomson types. For complete success everything depends in this case upon the equivalence of the self-induction in the armature and the field, upon the suppression of magnetic leakage, and particularly upon the lines generated in the armature traversing the iron of the field *in all positions of the armature* in preference to short-circuiting through air over the top of the coils. It would seem that these requirements must be excessively difficult to carry out, and also that the machine, when built, must necessarily possess some highly inconvenient features. M. Leblanc has, however, constructed or modified a Chertemps machine upon this plan, and with a current of 140 alternations he found that it "yielded an output proportionate to its size;" when, however, the period was shortened so as to give 300 alternations per second, the armature could not pass the dead

* The armature being, however, of the Siemens' alternating type.

† The value of ΔW is shown in the original to be

$$-\frac{E_0^2}{2(R+R')^2} \frac{M_1 \Delta M}{L},$$

where M_1 is the initial value of M. This can be made to approach as nearly as we please (on the lines already laid down) to the work done under similar conditions with a continuous E.M.F. of value $\frac{E_0}{\sqrt{2}}$.

Digitized by Google

points. As, however, the machine had only six pairs of poles and six armature coils, we should have been inclined to think it well-nigh impossible to maintain M even approximately constant. However this may be, the impedance was found to be greatly diminished when the circuit of the brushes was closed, quite in accordance with the theory above given. The author thinks that the Desrozier disc armature (described in *The Electrician* of October 19th, 1888, p. 762) would be well suited for this class of motor; and although "difficulties of construction," which are not further particularised, but which can easily be imagined, have induced him for the present to abandon the idea, the author still thinks, upon the whole, that at least from the theoretical point of view this solution is the best yet indicated. Those of our readers who read the description of M. Leblanc's latest motor in our last issue will recognise that he has since embodied the idea of balancing the field lines by the self-induction of the armature in a somewhat different and apparently a more successful form.

(To be continued.)

THE PARIS EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT).

August 12, 1889.

The Thomson-Houston Exhibit.

The Thomson-Houston Company have made a fine exhibit, which is larger than at first sight it appears to be, as it is somewhat scattered. Dynamos of different types, and varying from the largest to the smallest size manufactured by the Company are shown at their stand in the main avenue of the Palais des Machines. In the United States section of the Agricultural Court about nine machines are running for the purpose of transmission of energy, and two double-motor tramcar trucks are shown in the railway section.

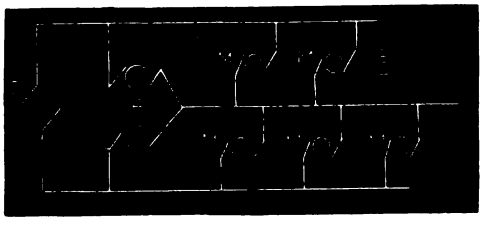

FIG. 1.

To anyone passing down the main avenue the most conspicuous object in the stand is the dynamo employed for the transmission of energy. It is the largest generator made by the Company, and gives 125 amperes and 500 volts. It has a drum armature, and the field-magnets are compound-wound, the shunt coils being wound in the usual way, and the series coils being fixed on to the extremities of the pole-pieces close to the armature, the two limbs being joined in parallel. From this machine the current is carried away to the Agricultural Courts on the Quai d'Orsay, about a mile from the stand. Here is a large shunt-wound motor of similar type and size to the generator, which drives a large dynamo of the well-known "Thomson-Houston" pattern. The current from this dynamo is supplied at a potential difference of 250 volts, and passes through a "potential equaliser" before reaching the motors, which are five in number. The "potential equaliser" is a machine somewhat resembling a shunt-wound motor in outward appearance, it has two separate sets of coils on the armature with two commutators and a pair of brushes to each. The theoretical connections will be understood from the diagram (Fig. 1). D is the Thomson-Houston dynamo, P the potential equaliser, M the motors. Although not the largest in point of horse power, this exhibit is one of the most interesting examples of the transmission and subdivision of energy by means of electricity to be seen in the Exhibition.

To return to the Palais des Machines. Four dynamos are constantly running to supply current for the various arc and incandescent lamps arranged round the stand and for the experiments with alternating currents shown at Prof. Elihu Thomson's personal exhibit in the Industrial Court. The largest of these machines is a 35-lighter of the well-known Thomson-Houston type, supplying energy for the arc lamps which are connected up in series with groups of incandescent lamps and arranged about the stand. The steadiness of the former is shown to advantage by this arrangement. Alternating currents are generated by two machines whose

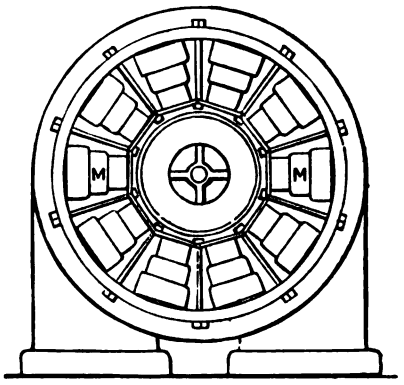

FIG. 2.—Thomson-Houston Alternator.

general form is shown in the sketch Fig. 2. In outward appearance they resemble one another, but differ considerably in the mode of exciting the field magnets. The circular framework (Fig. 2) with its internal pole pieces is cast in one piece. The armature is in the form of a cylinder built up of insulated rings, and the coils which consist of one layer only are placed flat on the outside and bound down in the usual way with insulated bands of wire. The spokes or spiders are set at an angle so as to act like a fan, causing a constant stream of air through the centre when running. The spindle is hollow, collecting rings are

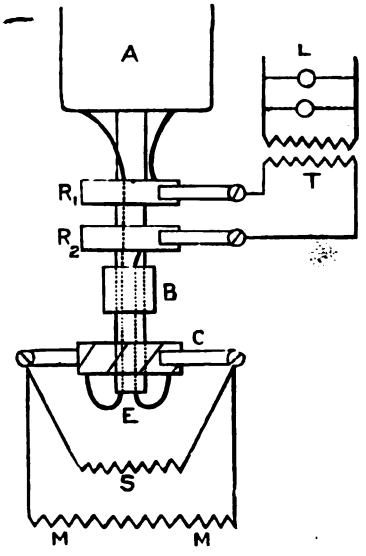

FIG. 3.—Diagram of the Connections of the Thomson-Houston Self-exciting Alternator.

placed on the inner side of the bearings next the armature and the commutator outside at the end of the spindle. The armature of the ten-pole machine, which is entirely self-exciting, carries two sets of coils laid over one another, one set being connected to the collectors and supplying the outside circuits, the other set being joined up to the commutator and feeding the field-magnet coils. The machine gives 20 amperes at a potential difference of 1000 volts, and is employed to run sets of 40 incandescent lamps in series. The eight-pole machine exhibits a different method of field-magnet winding; it

Digitized by Google

might be described as an alternating-series dynamo partially separately excited. The connection will be easily understood on reference to the diagram Fig. 3. The current on leaving the armature A passes from the collecting ring R_1 to the outside circuits through transformers T, it then returns to the dynamo, entering by the other collector R_2, and flows through the hollow spindle to the commutator C, that is outside the bearings B. From here it passes as a continuous current round to opposite field-magnet coils, in series, M M Figs. 2 and 3, and returns to

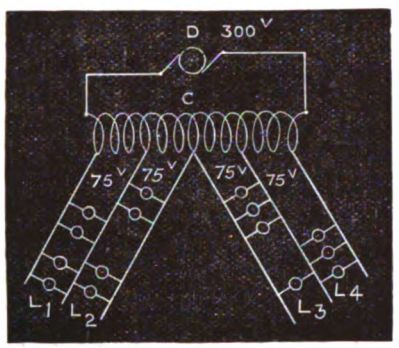

Fig. 4.

the armature by the hollow spindle. It is found necessary to shunt a small portion of the total current that would otherwise flow through the coils M M, ; this shunt is determined in the workshop and fixed in a convenient corner on the bed plate. The remaining coils of the field magnet are excited from another small machine, driven by a belt from a pulley on the end of the dynamo spindle outside the larger one, round which runs the belt from the main shafting.

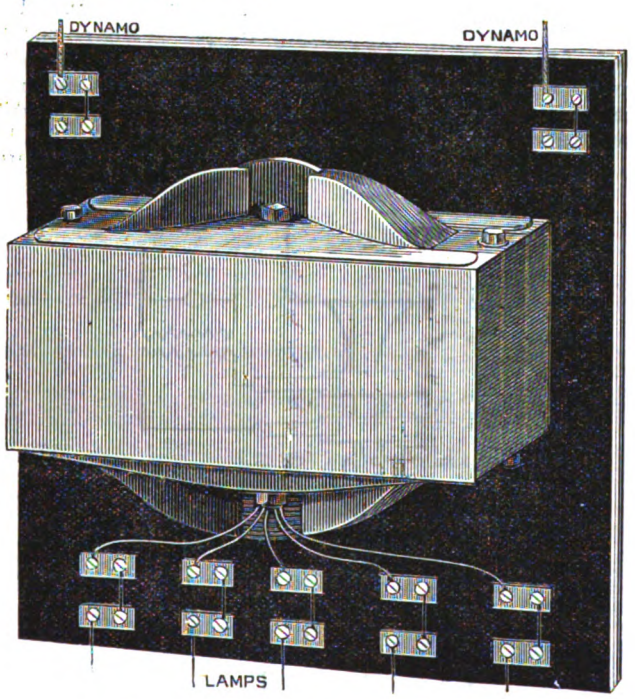

Fig. 5.—Thomson Houston Compensator.

The current from this machine is supplied at 300 volts, and is usually worked in connection with a "compensator." The theoretical connections of this arrangement are shown in Fig. 4. In Fig. 5 one of these "compensators" is shown fixed to a switch-board. The "compensator" consists of one continuous coil, surrounded by iron, as in a transformer, and connected to the dynamo. At equal intervals branches are led off for the lamps, as shown in Fig. 4. The circuits L_1 L_2 form one three-wire system, with lamps of 75 volts; L_3 L_4 form another similar system, with lamps of the same voltage.

The holder used for the incandescent lamps in series is fitted with a film "cut-out." In Fig. 6 we have a sketch of this arrangement. The leads are inserted through the top, and fixed to the terminals on either side of the circular brass frame F, Fig. 6. The central screw, W, is connected with one of these, and carefully insulated from the framework. The bent copper strip, C, is also attached to W, and prevented by the film of paper, P, from making contact with the frame. The other terminal, T, is in contact with the frame, F, and the flat spiral spring, S, which maintains contact with the other terminal through the copper strip at C, when no lamp is in the holder. On screwing in the lamp the ring R R presses S away from C, and thereby inserts the carbon between the terminals. If the lamp should go out the full pressure of the circuit is for a moment brought to bear on either side of the film P, which punctures, and the circuit is completed. Four or five extra lamps are arranged on the switch-board with a special switch, so that one of them can immediately be switched into the circuit by the engineer in charge when the instrument on the board indicates an increase of current, which results if one of the lamps in the series is cut out. This system is, of course, intended for street lighting or other installations where all the lamps are required at the same time.

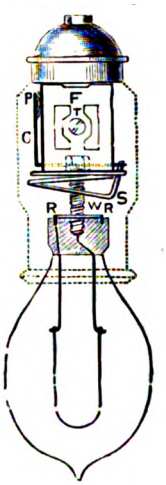

Fig. 6.—Thomson-Houston Lamp-holder for Series Circuit.

The double-motor tram-car trucks exhibited by the company in the railway section show the general form used on their electric tram lines. They differ slightly in one or two details. The latest form of suspending the motor is shown in Fig. 7, where projecting pieces from the motor M rest on an iron bar supported on large india-rubber washers, W, fixed to the iron frame F, instead of being fixed to a board resting across the framework of the truck. It is greatly to be regretted that the company had not an opportunity of exhibiting one of their tramcars in full working order, as it would have given the public a chance of trying a form of locomotion with which we are by no means too familiar on this side of the Atlantic.

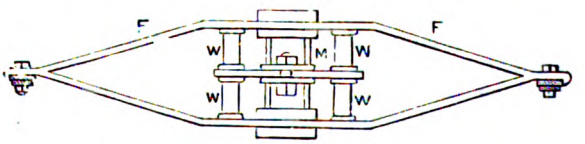

Fig. 7.—Thomson-Houston Method of Suspending Tramcar Motors.

The exhibit of the Thomson-Houston Company, under the management of Mr. Parsons, is practically separate from that of the Thomson Welding Company, which occupies part of the same stand, and which will be noticed at another time.

August 14, 1889.

The last meeting of the Conseil Municipal was almost entirely devoted to electricity. At the commencement the Conseil was occupied with the reading of a rather long report of M. Sauton relating to the present state of affairs, and giving the names of all the streets in which, up to now, underground mains have

Digitized by Google

been authorised, and where distribution must be begun before the end of next year. They amount in number to 140, with a total length of 170 kilometres, of which about 20 kilometres are at present provided with mains. Of the seven companies who demand concessions, only four, viz., the Secteur de la Place Clichy, the Société Marcel Deprez, the Edison Company, and the Popp Company, have complied with the conditions imposed on them and deposited the caution money. These concessions apply exclusively to the right bank of the river. The report states, however, that the Committee has in its hands two demands for districts on the left bank, which, on account of the short time they have been in its possession, cannot be presented to the Conseil and discussed before the October Session, when the demand of the Berthier Company, to be authorised to lay mains at Passy, Auteuil, and in the Champs-Elysées, will also be considered. After this the Conseil authorised the municipal administration to contract for the buying of two 90 kilo-watt Ferranti alternators and a corresponding number of transformers, but only on the condition that the whole of this material should be manufactured in France. As a matter of fact, the dynamos have already been manufactured at the Cail Works, Grenelle. This plant is intended for the municipal station at present under construction at the Halles Centrales, and which is to be ready to start on the 1st November next. As you are aware, a clause of the Cahier des Charges states that the whole of the plant, electrical or mechanical, wiring, lamps, fittings, &c, employed in or by the central stations, is to be manufactured in France and sold by French firms. Some members of the Conseil having been told that one of the Concessionnaires, which is said to be the Popp Company, had made some contracts for foreign material, steam-engines and dynamos, a Special Commission has been appointed to inquire fully into the facts, and report at the next meeting, when authorisations will be withdrawn from any companies using foreign material or having more than one-tenth of their workmen of foreign origin.

The newly-reconstructed Saint Lazare Station has been provided with a fine installation of the electric light, erected by the Société d'Appareillage et d'Éclairage. The plant comprises three Belleville boilers, capable of furnishing 2,000 kilogrammes of steam per hour; three 140 horse-power Lecouteux and Garnier engines, running at 180 revolutions a minute; each of these engines driving two 450-ampere 100-volt Gramme dynamos connected in series. Two of these groups suffice to do the lighting, the third being held in reserve. The leads are taken from the generating station to the distributing board at the railway station, 750 metres away, the cables being 200 millimetres in section, and in some parts lead-covered. The lights at present running consist of one hundred 10 and 16 candle-power incandescents, one hundred and fifty-three 400 candle-power and eighteen 250 candle-power arcs, but the plant is capable of supplying about 50 per cent. more lamps if required to do so. The arc lamps are all of the Cance type, and are run on separate circuits from the distributing board. The contract prices are five centimes per hour per incandescent lamp, and 30 and 40 centimes per hour for the 250 and 400 candle-power arcs respectively. The agreement between the Société d'Appareillage et d'Éclairage and the Railway Company lasts for ten years, and at the end of this period the Railway Company enters into possession of the entire installation without further payments.

The lighting of the Exhibition has very much improved, and can now be said to be a good, as well as an extensive, example of electric lighting. The jury of Class 62 have finished their labours, and the list of awards will be published at the beginning of next month. Mr. Edison arrived here on Monday from New York, and will probably stay in Paris till the opening of the Congrès International des Électriciens on the 24th inst.

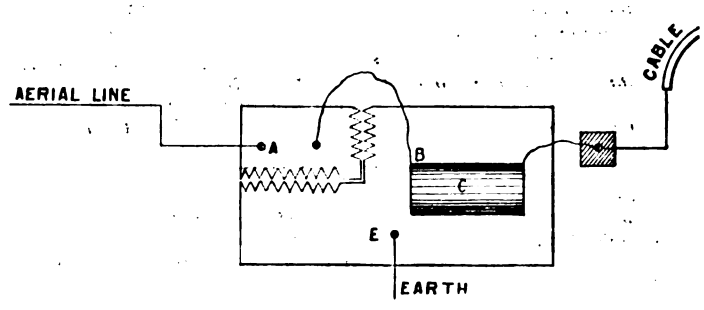
AN IMPROVED LIGHTNING PROTECTOR.

BY A. R. BENNETT.

Experience shows that fusion of coils of fine wire by lightning almost invariably occurs at the commencement of the winding, the high self-induction of the coil forcing a leap at that point, and when a convenient earth is at hand, as in the case of telephonic translators, the primaries of which are earthed, penetration beyond the first layer appears to be altogether unknown, the lightning preferring to jump down the inside of the cheek of the bobbin to the earthed primary. The fact suggests the possibility of constructing that long-sought desideratum, a lightning protector that will *always* protect, by combining a coil of fine wire with a serrated or plain plate discharger, as indicated in the figure, where C is such a coil let into



a rectangular slot in the metal earth-plate E. A is another plate, to which is attached the aerial line, and from which a fine wire communicates with one end of C, the other being to the cable or instrument to be protected. C might with great advantage be wound on a metal core and be enclosed in a metal tube or box, all forming part of or being in contact with the earth-plate E. Such an arrangement, which, so far as I am aware, is novel, would render the passage from coil to earth still easier than in the case of the translator, and would, I believe, be the nearest approach to a perfect protector yet devised, for, according to my experience, currents strong enough to do damage would never pass the point B, at which the winding of fine wire begins. The lightning would be bound to jump at B, and that point being entirely and closely surrounded by the earth-plate its further course would be determined harmlessly. The only disadvantage attending the arrangement would be the probable interruption of service by fusion at B; but as it is, I believe, the practice to earth cables on the approach of a storm—and it would be quite possible to have reserve coils ready to slip into place at hand—the inconvenience might be less serious than at present. The speed of signalling or efficiency of speaking would not be appreciably affected by the use of such protectors, as a few layers of closely-wound No. 40 wire would suffice, and the core, although preferably of metal, need not be of iron. Protection by the insertion of a fine wire in the circuit has long been known, of course, but the intimate association of the fine wire with an earth-plate I do not remember to have seen proposed.

LEGAL INTELLIGENCE.

Butler v. The Kensington and Knightsbridge Electric Lighting Company (Limited).

This was a motion by the owner of the house No. 148, Brompton-road, to restrain the defendant company, until the trial or further order, from using their steam-engines and dynamos and allowing noxious fumes to be emitted from their works, to the annoyance of himself and his family.

Mr. Renshaw, Q.C., and Mr. Maidlow appeared for the plaintiff.

The ATTORNEY-GENERAL (Sir R. Webster, Q.C.), with whom were Mr. Marten, Q.C., and Mr. Wallace, said the case was eminently one in which someone should go down and view the premises, and suggested that the case should go to the Official Referee.

After some discussion

Mr. JUSTICE KAY directed the case to go either to the Official Referee or to some special referee, being a barrister, to be agreed upon between the parties, or, failing agreement, to be nominated by the Chief Clerk, with power for the referee to grant an injunction and enter up judgment.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

'THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

"THE ELECTRICAL WORLD" OF NEW YORK.

Arrangements have been made by which "THE ELECTRICAL WORLD" OF NEW YORK *can be obtained from* "THE ELECTRICIAN" *Office, 1, Salisbury-court, Fleet-street, London, E.C.*

The Rate of Subscription (payable in advance), is **£1 1s. 0d.** *per annum.*

Single Copies of "THE ELECTRICAL WORLD" *can also be obtained,* **price 6d. each; post free, 7d.**

"THE ELECTRICIAN" *can also be obtained of the* W. J. JOHNSTON COMPANY (LIMITED), "THE ELECTRICAL WORLD" *Office, Times Building, New York, U.S.A.*

"THE ELEKTROTECHNISCHE ZEITSCHRIFT" OF BERLIN.

"THE ELECTRICIAN" COMPANY *are also Agents for* "THE ELEKTROTECHNISCHE ZEITSCHRIFT" OF BERLIN, *published Fortnightly, and copies of this well-known Electrical Journal can be obtained at the Offices of* "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, E.C.,* **price 8d., post free, 10d.** *The Annual Subscription is* **£1. 2s. 6d.** *(post free),* PAYABLE IN ADVANCE.

Subscriptions are received by this Company for all Continental and American Electrical Journals. Subscription Rates on application to "THE PUBLISHER." *Remittance must accompany order* IN ALL CASES.

LOCAL AUTHORITIES AND ELECTRIC LIGHTING COMPANIES.

In the present issue will be found a list of the Local Authorities throughout the United Kingdom who have received notice from Electricity Supply Companies (either general or local) of their intention to apply for a Provisional Order for that locality during the ensuing Parliamentary Session, together with the names of the companies concerned. We publish also a supplementary list showing the number of such applications made by each company. Our readers are aware that the period allowed by the Act for serving these notices expires each year on July 1st, so that the time has now come when at least the outside possibilities of electric lighting during the next twelve months can be fairly estimated. We have been at great pains to make this information as complete and trustworthy as possible, and to this end we have placed ourselves in communication not only with the companies concerned, but in many cases with the Local Authorities as well. We have to acknowledge the well-nigh uniform readiness and courtesy with which our applications have been met. At the

Digitized by Google

same time there remain a few instances in which, for one reason or another, we have been unable to obtain definite information. These are, however, scarcely sufficiently numerous to affect the general result. It will be seen that the total number of notices amounts to 479, of which as many as 115 have reference to the Metropolitan Area alone. Before proceeding to comment upon the significance (if any) which these figures may be presumed to possess, it will be as well briefly to analyse the list a little further, in order to see what the more important companies are doing, and upon what line of policy they appear to be moving.

Taking the Metropolis first, we find that the 41 notices of the London Electric Supply Corporation cover almost the whole of London within the four-mile circle from Charing-cross, whilst in some directions they extend to considerable distances beyond that limit. The Corporation proposes not merely to ask for those districts which were not scheduled in its earlier applications; but, refusing to recognise any finality in the recent Board of Trade report, it attacks those parishes which are already in the occupation of others, and from some of which it was lately excluded. The Metropolitan Electric Supply Company has adopted an altogether different policy. Its applications are only six in number, and in each case either the territory is altogether unoccupied, or else, as in the City and in Paddington, the company has already some kind of foothold in the district. That it will get its City Order is practically certain, and it is easy to see that it means business in the other five cases also. The House-to-House Electric Lighting Company having recently given birth to a numerous offspring (11 at one brood), is now confining its own operations to the immediate neighbourhood of the Metropolis. With few exceptions, its 20 applications relate to districts verging on or towards the outskirts of the metropolis, and it is only at Paddington, Lambeth, St. Pancras, Islington, Hackney, and Camberwell that it comes into direct competition with any of its more important rivals. In some half-dozen cases it seems to have secured uncontested territory. Proceeding further, we find that in 12 instances notices have been served by solicitors in the name of "A Company to be formed;" whether this is sufficient to comply with the requirements of the law we do not pretend to know. However, the "Company to be formed" seems anxious to illuminate the purlieus of Whitechapel, Bethnal Green, and Shoreditch, in which enterprise we sincerely wish them every success. Its notices, also, extend over an extensive and desirable area in the West, including Kensington, Paddington, Fulham, and Hammersmith. We have not space for any further analysis of the Metropolitan notices, but a careful perusal of our list will reveal some additional features of interest.

Turning to the Provinces, we are at once struck by the extensive show made by the various offshoots of the House-to-House Company. These companies are responsible between them for no less than 204 notices, and if we add the 20 Metropolitan notices of the parent company this amounts to nearly one-half of the whole number issued. It will be of some interest to see what percentage of these 204 notices are proceeded with during the year. The next largest undertaking (according to this standard of measurement) is that of the Electric Construction and Maintenance Company, which has issued 36 notices, ranging over the country from Dundee in the north to Falmouth in the south, and including such diverse localities as Edinburgh, Liverpool, Cheltenham, Croydon and Darlington. The South-Western District and Thames Valley Electricity Company has issued 21 notices, of which seven are Metropolitan. The Laing, Wharton and Down Construction Syndicate comes next with 14 notices, of which one is Metropolitan; the Municipal Electric Light and Power Corporation follows with 14, the Electric Trust with 12, and the Devon and Cornwall Electricity Supply Company and the Anglo-American Brush Electric Light Corporation with 11 each. The remaining companies may for the most part be divided into two classes: (1) Local Companies, of which outside London there are 21 in the list (including three existing Gas companies), and which for the most part issue single notices and must be supposed to mean business; (2) Companies with wide-sweeping titles, which (like some others already named) are as yet unknown to fame, but which in this case appear to have the good sense to commence operations upon a modest scale. Such are the Electric Lighting Maintenance Company with one notice, the Counties Electricity Supply Corporation with one, the National Electric Supply Company with four, and the Scottish Electric Supply Company with one.

Space will not permit us this week to attempt to draw any conclusions from the state of affairs which is thus disclosed, but we shall hope to return to the subject at an early date.

ELECTRIC LIGHTING NOTICES FOR 1889-90.

The following is a list of the Local Authorities who have been served with notices by Electric Lighting Companies for the ensuing year. In towns marked with an asterisk (*) the Local Authorities have decided themselves to apply for an Order or License, or are considering the advisability of so doing.

METROPOLITAN AREA.

Place.	No. of Applications.	Names of Applicants.
Acton	1	House-to-House Electric Light Supply Company.
Barnes	2	South of England House-to-House Electricity Co. South-Western District and Thames Valley Electricity Supply Company.
Battersea	1	Electric Construction and Maintenance Company.
Bermondsey	1	London Electric Supply Corporation.
Bethnal Green	2	London Electric Supply Corporation. A Company to be formed.
Camberwell	3	Electric Construction and Maintenance Company. House-to-House Electric Light Supply Company. London Electric Supply Corporation.
Chelsea	2	Chelsea Electricity Supply Company. London Electric Supply Corporation.
Chiswick	1	House-to-House Electric Light Supply Company.
City of London.	4	Anglo-American Brush Electric Light Corporation. Laing, Wharton and Down Construction Syndicate London Electric Supply Corporation. Metropolitan Electric Supply Company.
Clerkenwell	2	London Electric Supply Corporation. A Company to be formed.
Ealing	1	House-to-House Electric Light Supply Company.
Edmonton	1	South of England House-to-House Electricity Co.
Finchley	1	House-to-House Electric Light Supply Company.
Fulham	3	House-to-House Electric Light Supply Company. London Electric Supply Corporation. A Company to be formed.
Greenwich	1	London Electric Supply Corporation.
Hackney	3	House-to-House Electric Light Supply Company. London Electric Supply Corporation. A Company to be formed.
Hammersmith	5	Anglo-American Brush Electric Light Corporation. House-to-House Electric Light Supply Company. London Electric Supply Corporation. Metropolitan Electric Supply Company. A Company to be formed.
Hampstead	3	House-to-House Electric Light Supply Company. London Electric Supply Corporation. A Company to be formed.
Hanwell	1	Electricity Supply Corporation.
Hendon	1	House-to-House Electric Light Supply Company.
Holborn	2	Gwynne-Pilsen Electric Company (License). London Electric Supply Corporation.

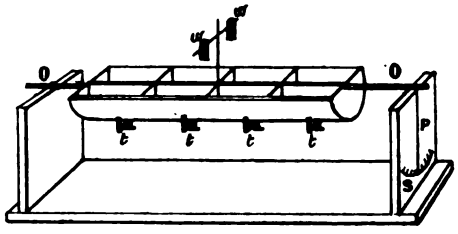
ON A MECHANICAL MODEL, ILLUSTRATING THE RESIDUAL CHARGE IN A DIELECTRIC.*

BY J. H. POYNTING, D.SC., F.R.S.

The model is designed to exhibit a phenomenon analogous to the residual charge which gathers in a condenser after it has been charged and then discharged, when the dielectric is not a perfect insulator. Its mode of action is similar to that which Maxwell supposes to occur in the dielectric. According to his theory the residual charge is due to the breaking down of the state of strain (or, perhaps, more correctly, of the stress) in the dielectric corresponding to the original charge, but in an uneven manner in different parts of the dielectric, so that just before the discharge the stress is greater in some parts than in others. On discharging, it is impossible, from the nature of electric discharge, to remove all the strain by connecting the two plates of the condenser, and the condition of equilibrium which is arrived at consists in an actual reversal of the strain in the parts where the breaking down has been most rapid, the reversed stress in these parts balancing the remnant of the original stress in the other parts. On insulation, the strain breaks down again, and at the greatest rate in the same layers, now reversed. Consequently the reversed stress is no longer able to balance the direct stress, and, on the whole, there is a preponderance of strain in the original direction, or a gathering of charge the same in kind as the original charge.



The model consists of a trough (*see* Figure) of semicircular

* Paper read before the Birmingham Philosophical Society, November, 1888.

cross section, 24in. long, 6in. diameter, and divided into eight equal compartments by a middle partition along the axis and three cross partitions. It is supported at the two ends, so that it can rotate about its axis O O, a pointer P attached to one end moving in front of a scale S. Four pipes, with taps $t\ t\ t\ t$, connect the opposite compartments when the taps are turned on. The trough is balanced by the weights $w\ w$, so that when empty it is in neutral equilibrium. Turning the taps off, and pouring in water to the same depth in all the compartments, the equilibrium at once becomes stable, and the trough, if displaced, stores up energy. It may be considered as analogous to a "tube of force," connecting charges $\pm q$ on the surfaces of two opposite conductors, the axis of the trough representing the axis of the tube of force, the angle of displacement the charge at either end, or the induction along the tube. A clockwise rotation at the pointer end might signify a positive charge at that end. As long as the taps are off the trough represents a perfect insulator, a displacement through a given angle, and fixture at that angle, corresponding to the communication of a charge and subsequent insulation. The energy remains in the trough undissipated. Discharge, of course, corresponds to release of the trough, and we have oscillations corresponding to the electrical oscillations brought recently into such prominence. It may be noted that a decrease in the quantity of water corresponds to an increase in specific inductive capacity, while a decrease in the weight of the trough corresponds to an increase in magnetic permeability. We might, perhaps, obtain an analogy to the spark discharge by completing the cylinder, of which the trough forms half, and carrying the partitions up through the added half. On turning the trough through anything more than a right angle it would fall over and oscillate about a new position 180deg. from the original one, the discharge of energy occuring now with an increase of strain, not with a return to the unstrained condition. If the taps are turned on, but all to the same extent, the trough corresponds to a "leaky" dielectric in which the conductivity is uniform. Turning the trough through a given angle, and holding it, the water begins to flow back from the higher to the lower compartments, thus dissipating the energy, and if after a short time the trough is released it returns to a position short of the original position, and remains there, the level of the water in the two sides of the middle partition being the same. But if the taps are turned on by different amounts—if, for example, the two end taps are turned off while the two middle ones are turned on, then turning the trough through a given angle and holding it the energy of the two middle pairs of compartments is gradually lessened, and on release the trough moves part way back. But now it is only the mean level which is the same on the two sides. In the two pairs of compartments with no communication there is still a positive difference of level, while in the other two there is now a negative difference. Holding the trough in its new position for a short time, the negative difference is reduced by leakage from one side to the other, and on release the trough returns by another amount towards its original position—and this may be repeated several times, until finally the original position is sensibly regained.

The first model I made, for ease of construction and without sufficient consideration, with rectangular instead of circular cross section; and with this the phenomenon of residual charge is obtained, even though all the taps are turned on equally. For consider what happens if the trough is turned through an angle and held. The water comes to a level after a time, but still its centre of gravity is not in the lowest possible position, and on release the trough returns part way, making a negative difference of level between the two sides. Again holding it, this difference is reduced, and on release there is another return, and so on. This suggests that possibly residual charge may occur not only when the substance is heterogeneous, and also when it is homogeneous, if with electric induction or strain there is both energy of the molecules as a whole and internal energy between the parts of each molecule. If the latter dies away after the bounding conductors are charged, the former may still remain, and on discharge it is possible that it may not all be dissipated, but may partly go to renew the internal energy. If this renewal accompanies a reversal of the direction of electric strain, we shall have the phenomena of residual charge.

It is hardly necessary to point out that the model serves equally as an illustration of a possible explanation of elastic after-action. It is evident that the phenomenon of residual charge will always occur when a body strained is such that the stress dies away unequally in different parts, while at the same time its constitution is such that on release from strain an equal amount of strain is taken from each part.

From this illustration of residual charge we may pass to a possible analogue of conduction in a metal wire. Let us suppose the trough replaced by a hollow cylinder, with its axis horizontal, ends closed, and without partitions. If the cylinder is only partly filled with water, a small couple applied to it will produce continuous rotation, but with a limiting angular velocity, attained when the water is dragged up in one side so far that the moment of its weight about the axis is equal to that of the applied couple. The energy put in by the couple is all ultimately converted into heat in the water. Thus the angular displacement increases indefinitely, though the stress always remains small. Similarly, as I believe, the "electric strain," or "induction," or "displacement" in a wire carrying a current increases indefinitely, as induction is continually coming into it from the outside, although the stress always remains small.

LIGHTNING, LIGHTNING CONDUCTORS, AND LIGHTNING PROTECTORS *

(Continued from page 356.)

In Mr. Symons' objection to laboratory experiments being regarded as at all analogous to lightning, and still more clearly in Captain Cardew's solemn protest in favour of the dignity of a thunderstorm and the absence of dignity from experiments conducted with tinplate, I seem to hear echoes of some fine old crusted objections which were current in the time of Franklin, and which were, perhaps, somewhat more in harmony with that time than with the present. Now that the subject has been mooted, however, I may be permitted to assert my conviction that the intrinsic dignity and solemnity of Nature is as present in a spark one inch, as in a spark one mile long; that, looked at with insight, a drop of ink hanging from a funnel† may be as inspiring an object of contemplation as a cataract; and that to explicitly claim special dignity for the one is implicitly to reject it from the other. True, one's subjective feelings of awe are not aroused in the one case as in the other, but that has to do with the relative size of the human body; and so far as an observer is overwhelmed or liable to have his nerves shattered out of existence by the phenomenon he is witnessing, just so far he is not in a perfectly collected and scientific frame of mind. Moreover, experiment under modifiable circumstances has enormous advantages over mere observation, especially observation which is only occasionally possible. Hence experiments in a laboratory and a thorough understanding of what occurs on a small scale are a very good introduction to the enlightened study of atmospheric electricity, though they are by no means to be regarded as a substitute for that direct study. So let me here emphatically admit and insist, in full agreement with what I suppose was the intention of these speakers, and with the more direct assertion of Colonel Armstrong, that experiments on actual lightning are highly desirable. Such experiments, as a sort of practical outcome of the Mann lectures, are, I hope, in course of establishment, by means of the bright idea of the editor of *The Electrician*, and by the enlightened co-operation of the Eastern Telegraph Company and Sir James Anderson. At foreign stations storms are frequent, and, with suitable appliances, I trust a record of valuable observations may be forthcoming in, say, five or ten years—without, let us hope, the "expenditure of any observers." The large number of photographic records of lightning which are now being obtained all over the country are likewise very valuable aids to progress.

Mr. Symonds is a determined and consistent advocate of large cross-section for conductors, maintaining that they are liable to be fused; and as this is a question of observation and experience of damage, I should be disposed to allow much weight to his opinion. Unfortunately, however, the two instances he adduces in support of his contention are not such as will bear serious examination,‡ since in one it is the links of a chain which are melted, and in the other the conductor is not fused, but merely "burnt by use."

Mr. Symons beautifully illustrates my remark that whenever a building is damaged it is always because the infallible rules of the Lightning Rod Conference had not been followed. The church at Garding was damaged because "they took the conductor down the *North* side of the steeple, not down the *wet* side, as we advised!"

With reference to his depreciatory observations on the Hotel de Ville, Brussels, and the Belgian School of Electricians, I shall leave them to speak for themselves. Mr. Symons will find that the death of M. Melsens has by no means removed from that country every man skilled in lightning conductor appliances.

I do not know who it is that has told Mr. Symons that all the lightning conductors "on the Houses of Parliament, Westminster Abbey, or wherever it may be, are wrong in principle and are dangerous." Certainly I have not. I have never either said or implied that a well-erected lightning conductor is other than a source of safety as far as it goes. I said in my first Mann lecture that the neighbourhood of a factory chimney is "a source of mild danger." And so I believe it is, even when possessing a good conductor. But, most distinctly, without a conductor it would be a

* From the *Journal* of the Institution of Electrical Engineers.

† Sir. W. Thomson's "Popular Lectures and Addresses," page 48.

‡ *See* Appendix III.

Digitized by Google

source of danger very much other than "mild." I never contemplated such a case, nor supposed that anyone would endeavour to increase their safety by pulling down lightning conductors.

Colonel Armstrong quotes several cases of damage wherein the earth resistance was found to be from 100 to 200 ohms. With all deference to his experience, I feel very doubtful if this amount of resistance is sufficient to account for the damage. I have admitted all along that the better the "earth" the better for everybody; but I have also pointed out numerous other reasons for failure and damage beside a bad earth.

In his most interesting observation of the cartridges exploded in a sealed metal case, we ought to be sure that the flash did not pierce, or melt, or ignite to redness, the case. Any violence of that sort might explode things in a very commonplace and unelectrical fashion. So also the violent shock due to expansion of air, or what Sir W. Thomson at Bath called the sound-wave, may be expected to have an effect on detonators.

Mr. Adams calls attention to the radiation of energy from conductors. It is most true that radiation goes on from all alternating circuits; and from linear oscillators like those of Hertz, or, what is essentially the same thing, from cloud and earth joined by a lightning conductor, the intensity of radiation is prodigious. It is a most important way of getting rid of energy; it is expended on the other at the rate of many horse-power. See a Paper of mine in the forthcoming July *Philosophical Magazine*. I am not sure, however, that the experiments of Mr. Adams illustrate this radiation very exactly. Nor do I quite understand his last sentence. If the facts be as he states, do they not place iron above copper rather than below it?

Mr. Spagnoletti's statements are most interesting. Mr. W. Groves, of Bolsover-street, tells me he has seen the alphabetical step-by-step machine worked two or three letters forward by atmospheric electricity of some kind on a wire between his place and Sir Charles Wheatstone's.

Mr. Evershed's observations on clouds go to support the conclusion that the well-known "return stroke," and such like observations, prove the conducting nature of clouds—of some clouds at any rate.

He is quite right in pointing out that all oscillatory character is liable to be wiped out of a discharge which has had to travel a great length of thin wire, and that the finding of a quiet tail of current leaking away in some obscure corner of a telegraph instrument is no criterion as to the vigour or character of the main flash whence it arose.

Passing to the criticisms communicated since the meeting, I have no special remark to make on the statements of Major Cardew except to say that several seem to be mere statements of peronals opinion, rather lightly and casually made.

With respect to No. 30, "We all know there are millions of volts," my point is misapprehended. It is familiar that there are millions of volts between cloud and earth; it is not familiar that there may be millions of volts between the top of a well-earthed and stout copper lightning conductor and the earth. When Major Cardew says, as he does towards the end of his remarks, under head "*Fourth*," that a conductor of small impedance is desirable, everyone must agree with him; but when he goes on to say that such a conductor is obtained by following the rules of the Lightning Rod Conference (or any other rules for that matter), it is necessary to disagree with him. The impedance could not be considered in any sense "small," even if a column of pure copper, a foot in diameter, was employed. The impedance of such a column, 100 metres high, to a current of frequency one million per second, is nearly 900 ohms.

Major Cardew twits me with having supposed that an earth resistance can be got as low as one-thousandth of an ohm, but if he chooses to refer to my Section 84 again he will find that I have supposed nothing of the kind. If I had said the billionth of an ohm it would have expressed precisely the same meaning.

The experience which Colonel Bucknill has had in connection with the War Office conductors, and the attention he has for many years given to the protection of powder magazines, render his practical remarks very weighty. I regret they are at present so brief.

And now I come to the remarks of the President himself. For such of them as are personal, I may be permitted to express to him my thanks. There is one point—that with reference to Article 56—where I wish to explain my meaning more fully.

My statement runs, "Flat ribbon has a slight advantage over round rod, but not enough to override questions of convenience." Now it is of course perfectly true that extent of surface diminishes impedance, that Snow Harris's hollow tubes were better than Faraday's solid rods, and that if only one single stout conductor is to be used, then tape is distinctly its best, as indeed it is then also its most convenient, form. But I wished to obtain small self-induction by splitting up the conductor into detached portions, making each portion fairly thin. For these small conductors, also, no doubt ribbon is electrically better than wire. But will it last as long? Is iron ribbon easy to obtain? So long as common galvanised-iron telegraph wire is so easy to procure, it seemed a pity to insist on any other shape of cross-section, especially since a ribbon of corresponding cross-section would have to be so thin as to be very liable to rust away. All this I had in my mind in writing Section 56. I had so frequently insisted on the advantage of large surface in my theoretical Papers that I thought it permissible to throw it over in the practical portion for solely practical reasons, *i.e.*, because to insist on it to the bitter end seemed to entail trouble and expense.

But, it may be objected, why then did I say that tape had only a *slight* advantage over rod? Well, it is a matter of arithmetic to reckon how much better a given tape is than a given rod. If I make no mistake this is the result.

The self-induction of a rod of sectional radius, r, is to that of a strip of breadth, b, both being of same length, l, very nearly in the ratio

$$\frac{\log 2l - \log r - 1}{\log 2l - \log \frac{1}{4}b - 1},$$

the currents in each case being of such rapid frequency as keep to the outer surface.

Now, unless the rods are very short, or unless the breadth of the tape is enormous—its thinness being likewise excessive, if it is to consist of the same amount of metal as the rod—this ratio is not much greater than unity; and the same will be the ratio of their impedances.

Similarly the difference between hollow tube and solid rod is not of any *great* practical moment in lightning-rod circumstances.

With far lower frequencies, such as 100 per second, when frictional or dissipation resistance is the important part of total impedance, it is an altogether different matter, and the advantage of tube or plate over rod is then enormous, as Sir William Thomson has so thoroughly brought home to everybody.

Suppose, as rather an extreme case, the ratio of self-inductions for tape and rod were as great as 2, then the tape would have half the impedance of the rod for currents of the same frequency. Such a case I have experimented on; but I should not like to insist even then on the use of the tape in preference to the rod if there were serious practical objections on the score of cost, unsightliness, want of durability, &c., to be made against it.

If there are no such objections, then tape by all means, and the thinner and broader the better.*

It may be just borne in mind that decreasing the self-induction goes to increase the frequency, and hence that if ever the conductor forms a large portion of the entire path of discharge, the advantage of reducing its inertia is still less marked, for the impedance depends only on the square root of L in that case.

The President misunderstands me in one place, where he thinks I have said that it is no use connecting conductors to water mains. I do not know whence this misunderstanding can have arisen; possibly from section 59, where I say, "A good and deep earth should in general be provided, independent of water and gas mains." This may not be perfectly clear, but my meaning was as follows:—

Have at least one independent earth, made by a well or other suitable means, in addition to water main connections. In other words, do not depend *solely* on water main connections.

Probably this is a counsel of perfection for the case of ordinary dwelling-houses, but for an important building I think it may be wise, for these reasons:—Mains are near the surface, and in some weathers the soil near them may have become dry. Also they ramify into the house and into other people's houses, and will therefore conduct any violent charge communicated to them partly into these places, where, by a branch flash to a gas pipe, damage may be done and gas ignited.

I have shown that well earthed mains can thus give off unexpected sparks at a fair distance, even when only a Leyden jar discharge is run into them; hence I feel sure that some cases of damage result from lightning being thus brought underground into houses.

Having a good independent earth in addition to water mains is not indeed a *security* against this source of danger, but it is a step towards it. I do not propose to avoid the mains altogether, because in so many places it is not practicable. Whether you connect to them or not, the lightning will go to them if it chooses, unless they are far away; and it is better to give it an easy path rather than let it fly through air or soil, and knock, or melt, or burn a hole in them. It may sound absurd to talk of lightning knocking a hole; but the concussion of air is so great as to produce all the effects of an explosion. I entirely agree with Colonel Bucknill, that damage is most usually done wherever an air gap is jumped. I think compo-pipes are mostly melted where a flash jumps to or from them than where it simply passes along them.

With reference to the load of coke, I was under the impression that it was cheap and easy. It is not novel, and there are dozens of other well-known plans, if any are handier.

Lastly, I come to the most interesting topic of all—the cart-

* *See* Appendix II.

Digitized by Google

ridges exploded in metal cases, mentioned by Colonel Armstrong (always provided that they were not merely ignited by heat), and the President's remarks thereupon.

Experiments on the effect of screens have gone on at intervals for some time in my laboratory. We can suspend a little elect trometer-like needle, charged positive at one end and negative at the other, inside a tinfoil-coated glass box, and can deflect i- by moving towards it a charged ebonite rod. But in order to succeed, the lid of the box must be so put on that a Léclanché cell shall not be able to ring a bell by conduction along the box. In other words, there must be a breach of continuity, or at least a very high resistance in the circuit. So soon as a Léclanché current can pass, no practicable motion of the ebonite rod can disturb the needle in the slightest degree. But there must be some limit to this. A stronger charge moved more quickly might do something so we have taken to firing charged bullets out of a miniature cannon towards the box. The bullets are no joke. They go slick through three inches of wood, and it takes a considerable thickness of earth to stop them. They can be charged and discharged, or reversed at appropriate stations, by passing through charged metal ; or they can be made to propel suddenly a permanently charged disc. But not a wink does the needle show. That only means that the tinfoil coating is too thick. We are going on to gold leaf, or a silver film, and so gradually thinning down till an effect is obtained. An effect *must* be forthcoming with a thin enough conductor, because one can go by gradual degrees to none at all. Liquid screens can, of course, also be employed, and probably quite a decent thickness of these will be fairly transparent. I would suggest, principally by way of query, that the action will be as follows :—

Let the resistance of a metal box to a current along it be R, then when a steady current (C) flows, a difference of potential (R C) will exist between its ends, whence electrostatic lines of force will radiate both inside and outside, and an electrometer needle inside will feel them. Now, instead of passing a current through the box, move an electrostatic charge, Q, with velocity, v, towards it. An electric displacement occurs which results in a momentary current, proportional to Q v, in the metal walls of the box, and to a slope of potential some specifiable fraction of R Q v which the needle may feel.

When a spark strike the box, a momentary current similarly exists in its coating.

Now, if the momentary current has no time to penetrate the entire thickness of the metal so as to flow in its innermost layers, then none of the slope of potential due to it can be felt inside the box, though outside it would be mixed up with the much greater direct action of the electrostatic charge. But if the covering is thin enough for some portion of the current to travel by its innermost layer, then an electrostatic disturbance will occur inside, which the needle, or a frog's leg, or a vacuum tube, or a microscopic spark gap, may be competent to feel. I may say, however, that frog's legs do not appear very sensitive to this class of effects. A zinc copper contact disturbs them vastly more.

Now, if the metal be iron, the depth to which the transient currents penetrate is very much less than it is in the case of non-magnetic metals ; hence a superficial layer, thick enough to make an effective screen if made of iron, might be a very imperfect screen if made of any non-magnetic metal. On the other hand, the resistance of iron is so immensely greater than that of non-magnetic metals to these transient currents, that if the layer were thin enough to permit an effect to be appreciated at all, the slope of potential to be felt might be greater than with copper, or even with tin or lead.

May I ask the President to be good enough to say if any or all of this is nonsense ? and, if it is not (being perhaps only what he instinctively had in his mind when he gave a hint about iron cages at Bath—the hint which he repeated in reply to Colonel Armstrong), then he will probably be able to calculate off-hand how much effect is to be expected in any given case, and to lay down rules whereby the disturbance liable to be felt through a given thickness of a definite metal can be at once calculated.

And now with respect to the "Practical Suggestions," which I provisionally made at the end of my Paper in order that they might receive the benefit of criticism, and between which and the main body of the Paper I have always drawn a clear distinction. Several have been criticised, and some have been shaken. May I quickly run over the list, indicating those which I still strongly uphold and those which I regard as doubtful ?

Nos. 51, 52, and 53, I suppose Mr. Symons would say, are "reprinted from the Lightning Rod Conference." They have, certainly, a fine ancient flavour of orthodoxy about them. But he would not have me throw over everything, both bad and good ! They seem to me good.

Nos. 54 and 55 I strongly uphold.

No. 56 I have indicated my reasons for provisionally maintaining. If they are bad reasons I trust the President will at once crush them out of existence.

No. 57 I regard as very important, especially its latter sentence. It is just one of the points wherein the rules of the future will differ from the rules of the past.

Nos. 59, 60, 61, 62 are very much open to discussion.

Nos. 63 and 64, I think, are sound. But very likely Colonel Bucknill's addition to 63 is an improvement.

No. 65 is very doubtful. There are, as Colonel Bucknill points out, very serious exceptions to it, even if it can ever be regarded as a rule.

Nos. 66 and 67 are sound, I think.

No. 68 is a fact. (This, Major Cardew will say, is "dogmatic." That also is a fact.)

No. 69 is a counsel of perfection : intended for powder magazines, not for dwelling-houses. Sir W. Thomson said it, or something like it, at Bath. It must be remembered, however, that "gasometers" are damaged when struck, according to reports in newspapers.

Nos. 70 and 71 are very doubtful. I throw them out as suggestions which experience must settle.

No. 72 is, I think, all right, but after the words "a load of coke" one may add, *or any of the well-known earth-contact arrangements.*

No. 73 has been wholesomely criticised. I think I am safe in still saying "it is not an unmixed good." But very likely the gain outweighs the loss. In fact, I have in the Mann lectures advocated the proceeding as good on the whole.

No. 74 I should be glad to be able to omit, but see no present chance of it.

Nos. 75 and 76 have been well criticised. I quite feel the force of the criticisms, and am glad to take refuge in No. 74. At the same time a righteous substitute for No. 76, if it be wrong, is very desirable. The middle part of No. 76 (a chimney with inside metal shaft) is a frequent and very difficult case. It embodies the advice which at present, for want of better, I give. Boiler firemen, engine tenders, and dynamos, would be apt to be damaged, I fear, if contrary advice were followed.

No. 77 is, I think, generally true, for such things as rain-water conduits under eaves, for picture rods, &c. ; not, of course, for a miscellaneous collection of metal objects.

No. 78 is, I think, right, if not too troublesome in practice. A crown of long points leaning well over into the smoke may do as well.

No. 79 probably belongs to Mr. Symons and the Lightning Rod Conference.

Nos. 80, 81, 82, 83 are intended to apply only to desperately important places : dynamite factories, petroleum tanks, and such like. They are, of course, perfectly open to criticism.

No. 84 is correct.

Nos. 85, 86, 87 are hints towards more elaborate methods of testing than the out-of-date plan at present in use. I call it out of date because it is based upon the untruth No. 57, and upon entire ignorance (very natural a few years back) of the great obstruction offered by good conductors. It is better than no testing at all, but it is extremely inadequate, in that it detects only one, and that a comparatively unimportant, kind of flaw.

Nos. 88, 89, 90, 91 have to do with lightning "protectors," and, I suppose, are orthodox and indubitable.

(To be continued.)

PARLIAMENTARY INTELLIGENCE.

The Select Committee of the House of Lords on the Metropolitan Electric Lighting Schemes.

THURSDAY, 8TH AUGUST.

Mr. FREEMAN, for the County Council, informed their Lordships that, subject to the preamble passing, it had been agreed between himself and Mr. Saunders to insert at the end of the first schedule ("area of supply") the words : "But excluding the following bridges over the River Thames, vested in the County Council, namely, Westminster, Lambeth, Vauxhall, and Chelsea."

Mr. SAUNDERS, Q.C., then continued his argument in favour of the Order granted by the Board of Trade to the Westminster Electric Supply Corporation.

The CHAIRMAN announced that the Committee were of opinion that the question of the Special Report by the Board of Trade which was raised on the first day was a matter which was not arguable.

Mr. LITTLER said he had hoped their lordships would not have decided that question without hearing him, as he felt sure he could convince the Committee that the special report had not been made.

Mr. SAUNDERS urged that the point had been argued on Tuesday.

The CHAIRMAN said he had announced the unanimous decision of the Committee, and they could not go further into this matter.

Mr. R. E. CROMPTON, C.E., of Messrs. Crompton and Co., was then called. In reply to Mr. Wallace, he said his company were the contractors

to the Westminster Company. The first portion of the works was sufficient for a maximum supply of 5,000 10 candle-power lights; and the second portion was to be capable of supplying 85,000 lights. That second portion was to be for the lower half of the district to which the Order applied. The boilers required for 5,000 lights were in position and had been tested. One of the engines and dynamos had been tested and was at work. A large battery of accumulators had been put down and was just on completion, and all the switchboards and other plant required for a central station were also in position and practically ready for work. He would say that about three-fourths of the work for 5,000 lights was completed; and that they would be ready to supply those lights as soon as they could possibly lay down mains in the street. He had seen the site and the machinery of the opposing syndicate. As far as he could judge it appeared to be a quantity of boilers and machinery put down in a stable, which was all very well as a temporary means of supply, but the space available which, he was informed, could not be extended, was not sufficient to supply the quantity of light required to make central-station lighting pay.

Have you as a contractor to the company satisfied yourself as to the *bonâ fides* of the promoters and the responsibility of the undertaking?—I have satisfied myself that our money is safe.

Cross-examined by Mr. LITTLER: They had not commenced lighting at present. He believed the Syndicate had lighted one hotel. It was quite possible that the Syndicate was not only supplying 840 lights, but was under contract to supply 600 more. He was of opinion that the Syndicate had spent absolutely nothing on the site. He thought it was quite possible they had spent £2,000 or £2,500 on the machinery. One of the Westminster company's boilers, which was 40 horse-power, was a new one, and the other which was a 20 horse-power came from his other works. Those boilers were set up about six weeks ago. They were being got in when the company was before Major Marindin. They had also one Willan's engine and dynamo, both second-hand. The maximum output of their present appliances was about 1,200 lamps. The engine and dynamo both came from the Kensington Company. They were transferred to the Westminster because the Kensington did not want any more of the smaller dynamos.

Might I suggest it was in order to make a show that you were doing something?—No; they were no longer needed. As a matter of fact, they did not belong to the Kensington Company, but to us. It was customary to commence a station with small sets of plants, and the Westminster Company's station was put down in exactly the same way as the Kensington was started. There was room in their site for 2,800 horse power boilers. For the plant actually on the site his firm would receive altogether £4,700.

Mr. JOSEPH BROWNE MARTIN, in reply to Mr. SAUNDERS, said that he was one of the directors of the Westminster Company which was composed of people locally interested. He himself was a large freeholder in Westminster, and himself and two other members of the company paid about £9,000 a year in rates. The capital of the company was to be £100,000, and he had not the slightest doubt that if the Order was passed, they would be able to start the concern as a going concern. The Vestry of St. George's Hanover-square was supporting them in their district.

Have you any doubt whatever that if this Order is obtained in its present form you and your friends will be able to take up the whole of the capital?—Not the slightest. I and my friends are prepared to put in £50,000. If they do not put it in, I will put it in.

Mr. JAGO, Secretary to the Company, and Mr. JAMES LATIMER CLARK also gave evidence.

On behalf of the opponents, Mr. Littler then called Mr. THOMAS STANLEY PEACH, Chairman of the Syndicate, who produced the Memorandum and Articles of Association, and the register of the company. They had about 25 shareholders. £10,000 had been subscribed up to the present time—all paid up. They were registered within 11 days of the other company, but too late to go then for a Provisional Order. They had done a large amount of work beforehand. They were supplying about 1,500 lights, and had contracts for a good many more.

By the CHAIRMAN: They did not appear before Major Marindin because they were advised that without the consent of the Vestry, or without the approval of the Vestry, it was useless for them to make any application whatever, and therefore as they could not get the consent of the Vestry at that time, they decided that it was useless to put in an appearance.

Mr. COOPER, Electrical Engineer to the Syndicate, said the Company was incorporated in the month of July last year. They commenced lighting on the 15th September, and they had ever since that time supplied 750 lamps to the Hotel Windsor, at an agreed rental of £1,200 a year. They also supplied other customers, and had arranged to supply to St. Ermin's Mansions 230 lamps, and eventually about 1,600 to 2,000 by meter, or at £2 per lamp per annum. They had also arranged to supply the Member's Mansions for a period of eighteen months certain with 150 lamps at the rate of 30s. per lamp per annum. The Syndicate had expended no money whatever in wiring the buildings, and they had not canvassed for custom. About £4,400 had been spent on their electrical plant, including cost of machinery, cables, and the half-year's rent. They were charging on an average 7¾d. a unit. They had received from the vestry of St. Margaret's and St. John's, Westminster, their consent to the Syndicate applying for a license. He had visited the Westminster Company's works. He saw there a boiler which he took to be of 30 or 35 horse-power, and another one which might be of 20 horse-power. The 20 horse-power boiler was rather an old one. There was an engine there which had also apparently done a great deal of service, and a dynamo capable of giving current for about 500 lamps. The boilers were locomotive boilers, and might have cost a matter of £600 when they were new. The dynamos might have been a 20-unit machine or thereabouts, and might have cost something under £500 when new. The machine which they had was apparently a shunt-wound machine. He saw no cells, but the output of the machine would enable about 500 lamps to be supplied.

I suppose that apparatus would be sufficient to supply the one large building in which it was fixed?—Yes. I should think that the machinery that I saw would be very well suitable for lighting the Victoria Mansions. The room was not more than 15ft. wide, and the apparatus was only sufficient for the supply of the house in which it was. Unless they had a large number of cells, they had not more power that was necessary to light up Victoria Mansions.

Cross-examined by Mr. SAUNDERS: It was a mistake to say that they were supplying 1,500 lights; but they were under an agreement to supply 1,500 lights, and that number would be very much increased as the tenants applied in the buildings, which the Syndicate had got a monopoly to light. The actual maximum supply that they had at any time given was 880 lights.

Neither my scientific adviser nor myself can quite understand how £1,200 per annum for 750 lights is equivalent to 7¾d. per Board of Trade unit. Is it not the fact that that would be equivalent to 2s. per Board of Trade unit?—It is for a large number of lamps used all day, and in dark passages.

If Mr. Crompton's calculation is correct, that cannot make the difference, unless you use it three times as long as the ordinary house term?—I understood the question to be what our price was per meter.

It must not be supposed that the Windsor Hotel is getting the benefit of that 7¾d. rate?—It is not.

What is it that you are afraid of if we get our Provisional Order, and carry it out?—We believe that your company intends to run on the three-wire system as a permanent engineering work, and we intend to do the same, and we apprehend that the two companies supplying on the same system will not be allowed to compete in one and the same district.

In other words, you apprehend that it is either your company or our company that is to supply the district, and not both?—That is so.

In reply to further questions, WITNESS said that he did not go into the storage battery room of the promoters' works. He believed that they had 60 cells, but he did not see them. His own company had a storage battery, not in their works but at the Windsor Hotel, by means of which they supplied other consumers besides the hotel. The company was not connected with the Hotel Company, but in order to enable them to supply their customers all day and all night, and to avoid running the machinery with an extremely light load the whole 24 hours, they had one battery which was sufficient to do all the night lighting at the Hotel Windsor, and also to meet any call that might be made upon it by any of their other customers. The battery was placed in the Hotel Windsor because they were offered a very convenient position, but they had space for it in their own premises, and he wished that it was on their own premises now.

Re-examined by Mr. LITTLER: Works for works, which of the two at this date is most capable of supplying electricity?—Our Company.

By the COMMITTEE: They could not pretend to do as much on their site of a quarter of an acre as could be done by other people on a site of half-an-acre, but in selecting their site they were of opinion that with the space they had at present and the space they had the right to acquire, there would be room enough to meet all the requirements of lighting the district. They considered they could put down plant for 90,000 10-candle lamps.

Mr. SAUNDERS informed the Committee that as the Order was not opposed with regard to St. George's, Hanover-square, he had not gone into the circumstances in that district; but as a fact they had in that district a variety of other sites which would be interchangeable to supply the whole district.

Mr. PEACH (recalled), in answer to the CHAIRMAN, further explained that the reason why the Syndicate did not appear at the Board of Trade Inquiry to oppose the application for a Provisional Order by the Westminster Company was because they believed that without the approval of the Vestry or the consent of the local authority no Provisional Order or License would have been granted, and also because they did not think that the other Company were at all earnest in their endeavours to go on. They thought it was more or less what is called in America a "bluff," because the other Company made several overtures to his Company to join them.

The CHAIRMAN: I would point out that they might have appeared to oppose as persons locally interested.

Mr. LITTLER: I am bound to say, my lord, from what I know of local inquiries, that I should have advised them not to oppose. It is a great waste of time and of money too, because if they want to oppose they have to come here afterwards.

The WITNESS: We believed that that inquiry would end in nothing, and we did not want our shareholders' money to be wasted in attending those sort of things.

Mr. LITTLER then addressed their lordships on behalf of the Westminster Syndicate, contending that if the Order was refused to the Westminster Company the promoters would really lose nothing, but if it was granted the Syndicate would virtually lose the whole of the money they had spent; they would, in fact, suffer annihilation. The Syndicate was at the present moment the only electric company which was supplying the district. They were increasing their lighting orders every day, and were in a position to-morrow to supply light. The promoters were not. They had only started to attempt to supply. Was it intended that an Order should pass under such circumstances? The Syndicate had actually put down £10,000, but the promoting company had only put down £35, and the Syndicate was now being asked to sacrifice their £10,000 in order to make the promoters' £35 worth £25,000. That is what the Committee were asked to do at the instance of gentlemen who had done nothing until they thought they were tolerably safe, and now the company was stepping in, not only to destroy the £10,000 which his clients had put down, but to reap all the benefit from their efforts.

Mr. SAUNDERS replied, contending that the points raised by Mr Littler should have been raised before Major Marindin.

Digitized by Google

The Committee, having deliberated in private, decided to go on with the Order.

Mr. LITTLER then on behalf of the Syndicate asked the Committee to insert the following clause in the Order, which was similar to a clause which the London Company had agreed to give them :—"The Undertakers will not directly or indirectly oppose the procuring of a License or Provisional Order by the City of Westminster Electrical Syndicate (Limited), except so far as such License or Order may physically interfere with the works of the Undertakers, and the securing of protection from such interference." He said that such a clause was necessary to protect his clients from ruin. The £100,000 of capital which the promoters of the Westminster Company were entitled to raise would not be sufficient for the large area they proposed to supply, and that was all the more reason why his clients should be allowed to remain in the district.

Mr. SAUNDERS, for the promoters, stated that the clause had been accepted by the London Company by arrangement only, and he should object very strongly to its being compulsorily put upon his clients. The mode of supply adopted by the Syndicate was different in character to that adopted by the London Company, and therefore they would come within the definition of Major Marindin's report of two companies supplying by different systems for the purpose of competing and trying the two systems together side by side in the same district—one admittedly capable of giving motive power, the other doubtful upon that point. Both his clients and the Syndicate were equally capable of supplying motive-power, as they supplied by the direct current, and therefore there could be no real reason whatever why the two companies should have concurrent rights of supply in the same district. The principle upon which the Board of Trade had gone hitherto was not to give more than two companies the right to supply in the same district, and his clients could not therefore be put in the same category with the London Company, for the reason that if they were to do anything which would have the effect of admitting the Syndicate there, they would be doing that which the Board of Trade themselves did not approve of. He did not think such an arrangement as that now asked had ever been effected compulsorily, but he knew it had been done by agreement.

Mr. LITTLER, in reply, said that it had been done compulsorily, and added that he was quite ready in the proposed clause to put the words, "on the ground of competition."

The room was then cleared, and the Committee deliberated in private.

On the counsel and parties being called in,

The CHAIRMAN said: The Committee are not prepared to insert the clause.

The clauses of the Order were then gone through and agreed to, and the Committee closed.

HOUSE OF LORDS.—THURSDAY, AUGUST 15.

Yesterday, in the House of Lords, on the third reading of the Electric Lighting Provisional Orders (Nos. 2, 3, 4 and 5) Bills,

LORD CRAWFORD said although very great care had been exercised in drawing up these Bills still, in the course of time, they would have to be amended by their lordships. The parts of the Bills that would require amendment were the meter clauses and the testing clauses, and all those who had anything to do with electric lighting knew that they were unworkable. They were drawn up in 1882, when the first legislation on this subject took place, and they had been copied almost verbatim in the present Orders. They had had no time to modify them because nobody knew how to modify them. They were quite unworkable, and although he wished to recognise that great trouble had been taken over these Orders, still they could not be taken as final.

The EARL of LIMERICK said his noble friend would not expect him to go into this subject. These Bills were opposed before a Private Bill Committee, and it was agreed that this question of the meter should not be raised before the Committee. As his noble friend had said, it was a question for the future, and it had been put by his noble friend rather as a saving clause than as anticipating any action at present by their lordships' House.

The Bills were then passed.

THE BRUSSELS ELECTRIC TRAMWAY.

On the occasion of the visit of a party of electrical engineers to Brussels, for the purpose of studying the working of the electric tramways, which have now been running there for two years, M. G. Michelet, Director of the Brussels Tramway Company, read a Paper upon the experience gained during these two years. The following is the substance of M. Michelet's remarks :—The system adopted in Brussels is, as is well known, the Julien, and the promoters of this system stated in their prospectus that the tractional expenses would not exceed 16 centimes per car kilometre, this figure being calculated to apply to certain fixed lines in the Quartier Léopold, and on the assumption that the depôt in Rue Juste Lipse was to be arranged for the working. The Brussels Tramway Company, on the other hand, estimated the cost of working the lines in question, with two-horse cars, at 25 centimes per kilometre. The difference in cost was so great that had the calculations of the electrical promoters been true a great saving would have been effected. Experience soon proved that the batteries first employed were too weak. They were so rapidly destroyed that the duration of the experiments became a mere question of time. Experience taught us that the working of the tram in the Rue de la Loi, with a gradient of 1 in 30, requires a current of 30 amperes, and that in the Rue Juste Lipse, with a gradient of 1 in 25 for a distance of 480 metres, one of 40 amperes. It was therefore necessary to have cells weighing from 20 to 25 kilogrammes if the accumulators were only to develop two amperes per kilogramme, the allowable maximum. With regard to the electrical machinery, we are at present using dynamos of English construction, which answer very well. The cost of maintenance, however, still remains very high, and we are far from having attained the results anticipated. Thus, the expense of maintaining the accumulators, which was estimated at 3·51 centimes per car kilometre, costs at present 9 centimes, whilst the maintenance of the car motor and the transmission apparatus was estimated at 2·16 centimes, but is, in fact, 5·74 centimes ; in short, general expenses of every kind, except *employés*, are about 25 centimes per car kilometre, or very nearly the same as for working by horses. There is, therefore, on taking into consideration the maintenance of the stationary engines, royalties to the inventor, interest on the capital sunk, besides depreciation of fixed and rolling stock, a loss in working by electricity. The Brussels Tramway Company at present maintain only three electrical cars at work, though the installation is capable of working eight cars. In order to ascertain with perfect accuracy the expenses of the working the most minute control was instituted. During the past six months the Brussels electrical trams have run 61,088 kilometres, or 288 kilometres daily, and on this running the figures are based. It has been found very difficult to fix exactly the expenses of maintaining and renewing the accumulators. We estimate at present that the accumulators before requiring renewing are capable of working 8,000 kilometres, or 200 days ; at the end of this period they have to be taken to pieces and the positive plates renewed. The most careful attention has been given to this operation, and we have come to the conclusion that the expenses amount to 10 centimes per kilometre run. A special account has been opened for every battery where they have been credited every month with 10 centimes per kilometre run until the value has been reduced to that of the materials remaining. On the other hand, the account has been debited with all expenses of maintenance and renewal. The result of this careful bookkeeping in connection with monthly stock-takings is that the expenses of maintenance of the accumulators has been 9 centimes per kilometre. Our present efforts are wholly concentrated upon reducing the cost of maintenance of the accumulators and in improving the electric and mechanical apparatus. M. Michelet concluded by saying that he considered electric traction still in its infancy, and that practical experience had by no means justified the sanguine tone adopted at the Antwerp trials of a few years ago.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 3, 1889.

The march of events in this country is generally rapid, and a remarkable evidence of the speed with which changes and transformations occur has just been given in the action of the West-End Railway Company of Boston in regard to the wholesale adoption of electricity for its enormous system in Boston. Less than two years ago, shortly after the time when the street railway systems of Boston became concentrated under one management, Mr. H. M. Whitney, the president of the road, an energetic, enterprising, and far-sighted man, thought it worth while to experiment with electricity. He had noticed the improvements that were being made in electric motors, and had been somewhat impressed with the reports that reached him as to the successful operation of the few roads started. As was natural, his first impression was that the use of the storage battery would solve the problem for Boston. The horse-car service had been found inadequate, the use of the cable was almost out of the question in a city with so many winding streets, the prejudice against overhead wires was strong, electric conduit systems had been by no means perfected, and the choice, if choice it could be called, narrowed itself down to storage batteries. Mr. Whitney thereupon began to experiment, and proceeded to see what storage batteries could do. Somehow or other, and although the tests were in good hands, he did not derive much satisfaction from them, but while the use of electricity in this particular form disappointed him and his associates, they were convinced that the overhead

Digitized by Google

system, whose success had meanwhile been strikingly exemplified at Richmond, would answer their purpose. Accordingly, one or two of the suburban lines were equipped, first with the Sprague and Bentley-Knight systems, and then with the Thomson-Houston. The result has been that after a trial of five to six months the West-End Company has unanimously voted to increase its capital stock by four and a-half million dollars, in order to equip its whole system electrically. The reasons which Mr. Whitney presents for this highly important and significant step must be regarded as more than ample. To begin with, he shows that the cars operated by the overhead wires in Boston make one-eighth faster time than do the trains on the elevated roads in New York. Moreover, there has been a remarkable saving in the cost of motive-power. With horses, power has cost over ten cents per mile, whereas on the Alston electric line, in spite of much leakage on the section of conduit used, the cost has not exceeded five cents per mile, although, as has been noted, a much higher rate of speed than formerly has been attained. Then, as to the increase of travel, some wonderful statistics are given by Mr. Whitney in the able speech which he made before the West-End stockholders last week. On the Arlington electric line the traffic has shown an increase of 150 per cent. in seventeen days. Of course, it might be said that this was simply due to the novelty of the thing, but electric roads are not a novelty now in Boston. Moreover, on the Cambridge electric road, which has been running since 1st February, the increase in traffic reaches the astounding figure of over 300 per cent. Nothing could speak more strongly as to the boon which has been conferred by electric locomotion upon the citizens of Boston and its suburbs. In fact, Mr. Whitney appeals to the inhabitants for confirmation as to the statements that he makes about the greater comfort and convenience offered by the electric service. It might be expected that considerable opposition would be developed against the use of overhead wires, and, in fact, there has been a great deal of trouble on that score. But it does not come from the leading newspapers nor from the mass of the people. The overhead electric railway wires in Boston are practically unnoticed. I have myself ridden on the electric railroads there, and although I am pretty familiar with the electric roads in this country, I must confess that in Boston city, as well as in the outlying regions and in other places like Richmond, it is often difficult to discover at all the presence of the wires. In some of the Boston suburbs, too, the tracks, as well as the overhead systems, elude observation in an extraordinary manner. While the wires run through the trees the tracks are laid along stretches of green sward, with the grass growing beneath them, so that at a few paces' distance the rails cannot be seen at all. The effect is that of a car running upon grass without anything whatever to propel it. The cars on the various branches as soon as they escape the city limits are speeded up until they make from 10 to 15 miles an hour. The result is that the residents in the suburbs of Boston reached by the electric system are much nearer their business offices than they who live up town in New York along the line of the elevated roads. Another important point that Mr. Whitney touched upon was the depreciation of rolling stock. He showed that in spite of the defects naturally incident to a system that may be said to have reached a practical shape only within the last two years, the repairs and depreciation were quite low, and would compare very favourably with the depreciation on account of horses. The West-End Company has now to write off every year no less a sum than $150,000 for depreciation of its animal power. Allowing that the company paid the high price of $150 per horse, this would mean that at least a thousand horses a year are lost, or one in every seven, and we know very well that the improved electric motor can make a much better showing than that. It now remains to be seen what will be the result elsewhere of the action taken in Boston. In New York it is very unlikely that the overhead system will be adopted, but there are many other large cities throughout the country where the action of a crowded and conservative place like Boston will have a marked effect in hastening the adoption of electric roads with overhead wires. The street railway companies will certainly be stimulated by the statement made by Mr. Whitney that while the electric roads had been showing this enormous increase in traffic, the increase under the old system of horses had been only 10 per cent. annually. A more striking demonstration of the manner in which the use of electricity has fostered and developed travel cannot possibly be afforded.

In a recent letter I mentioned the fact that the Postmaster-General, exercising the power conferred upon him by an old Act, of regulating and revising the rates paid by the Government to the telegraph companies for official business, had cut down the tariff this year to the absurd figure of one mill per word, or one-tenth of what it had been before. Even at the old rate of a cent a word, the telegraph companies were by no means overpaid, but the new rate is not even enough to pay the messenger delivering the telegrams. It need not be wondered, therefore, that the Western Union Company has made a very stout protest against this new Government tariff. Postmaster-General Wannamaker has sought to justify his action by claiming that he was getting no more than others got, by which he is supposed to refer to the News Associations and to the railway companies; but even in this respect he is wrong. It is true that the telegraph companies have a limited free service for railway companies, but it is paid for in a variety of ways, including free transportation and maintenance of lines and the service of the railroad operators. With respect to the transmission of news, it is pointed out by Dr. Norvin Green that this is not exacting and that it is done mostly at night when the wires are clear. As Dr. Green says, outside of this the Western Union makes no reduced rates to any corporations or other patrons, large or small. For messages transmitted and delivered to a single address the Government is the only customer enjoying reduced rates. As for the claim that the company derives great benefits and privileges under the Act of 1866, Dr. Green replies that they are purely imaginary, and where occasion has arisen to cross Government land, the company has had more trouble and delay than if the property had belonged to private parties. The Western Union Company, in its fight against the Postmaster-General, has enjoyed the support of many of the journals that are noted as a general thing for their readiness to take up the cudgels against the company, and hence it may be hoped that the justice of the protest will be admitted and that the old rate will be restored. Otherwise, it will hardly pay the Western Union Company or any other telegraph company to make a book record of the Government business. It would be better to save money by not attempting to collect the paltry sum that the whole business would amount to in a year.

Many of your readers will, doubtless, be interested to hear that the Electrical Exhibition, which has just been held at St. John, New Brunswick, is voted by those who have seen it very much of a success. It is said that this is the first electrical exhibition ever held in a British Colony, and whether that be so or not, it is decidedly creditable to the city of St. John, in which it has been serving as one of the means of celebrating the practical completion of the Canadian Pacific Railway, which now gives Canada a road from the Atlantic to the Pacific. Its remarkable feature, however, as illustrating the closeness of business relations between this country and Canada, is that the Exhibition is largely made up of American manufacturers. In fact, the leading exhibits are those of the Edison and Brush companies. Although St. John is in many senses a remote place, it has a good appreciation of electrical applications. It has a good telegraph and telephone service, and already has two arc light plants, one Brush and the other Thomson-Houston, the latter being operated by the Gas Company. It is now stated that one of the results of the Exhibition will be that a new incandescent plant for general supply will be established in the city. Speaking of Exhibitions reminds me that electricity is playing a leading part in shows going on or projected at Detroit, Michigan, and Dallas, Texas, and that already over one thousand exhibitors have engaged space for the Electrical Exhibition to be given next month at St. Louis. All these efforts are excellent and do much to promote the welfare of electrical industries, but they will sink into utter insignificance alongside of the display which will undoubtedly be made in this city in 1892 on the occasion of the Exhibition to celebrate the discovery of America by Columbus, four hundred years ago. After all, Columbus did not do any more for

Digitized by Google

the race than such men as Morse, Edison and Bell have done, and it is fitting that the great feature of the Exhibition of 1892 should be the bringing together of all the electrical inventions and improvements of the century.

Next week the electric light men are all going off on a junketing trip to Niagara Falls to attend the meeting of the National Electric Light Convention. A very interesting programme of Papers and topics of discussion has been prepared, but, as the ladies also turn out in force on this occasion, I have no doubt that a great many of the members will find it more necessary to study the question of utilising the vast water power of Niagara by excursions out to the "Three Sisters" and trips on the "Maid of the Mist" than by exchanging experiences in a dusty and stifling hall. These meetings have a very good effect in bringing men together from all parts of the country to exchange ideas, and the benefits that are derived are not to be judged of merely from the list of Papers, no matter how vital may be the topics or how prominent the authors. In point of fact, a man would very often learn of more to his advantage at such a meeting from the merest casual conversation with his fellows than from the long discussions that may take place in regular session, where many of the men are afraid to speak out lest their facts and figures should get into print, and so "give away the business." I think that the rapid growth of electric lighting in this country may be in a great measure attributed to these gatherings, and I have no doubt that sooner or later something of the same kind will be tried with advantage in England, where by this time there ought to be, it would seem, enough encouragement in the electric lighting industry to constitute the nucleus of a convention of the kind we are now so familiar with here.

CORRESPONDENCE.

THE KNOWLES STORAGE CELL PLATE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 9th you call attention to a form of "storage cell plate" and a so-called "system" claimed by the Mutual Electric Manufacturing Company, the supposed chief points of novelty being described as:—

1. The use of a compound plate made by rivetting together two perforated sheets of lead with the active material packed between them.
2. An inoxidisable alloy.
3. An arrangement for working arc lamps and charging storage batteries with the same dynamo and conductor.

I would venture to point out, as to the first point, that such a compound plate is fully described and illustrated in my patent of September 10th, 1881, No. 3,926. As to the second, that the only inoxidisable alloy of a practicable nature for such work known up to the present time is formed of lead and antimony, described and patented by me under date September 15th, 1881, No. 3,987; and as to the third, I would refer those interested to my patent No. 217, 13th January, 1883, for "working and regulating secondary batteries," in which, under the head relating to circuits, in which there is a combination of arc and incandescent lamps and accumulators, I fully describe an arrangement which, so far as I gather from your brief description, anticipates that referred to.

With regard to the absence of "buckling and sulphating" claimed for the "novel" form of plate, surely the time is long passed for putting forward these bugbears. Any manufacturer who understands and attends to his business will send out plates properly made and fully "formed," and such plates, worked under well known and simple rules of treatment, will never buckle or sulphate injuriously, whilst, on the other hand, *no form of plate whatever* will escape one or other of these evils if either badly made in the first instance or badly treated afterwards.

Plates of the ordinary E.P.S. type, made early in 1882, have worked continuously and at full duty for many years without ever showing the least sign either of buckling or of becoming unduly sulphated, evidencing that any so-called recent improvements in manufacture have little to do with the prevention of these easily avoidable troubles.—Yours, &c.,

Sydenham, August 12th, 1889. JOHN S. SELLON.

MR. MORDEY'S PAPER AND THE DISCUSSION ON ALTERNATE-CURRENT WORKING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 2nd inst. I notice a reproduction of Mr. Mordey's reply to the discussion on his Paper, "Alternate-Current Working," in which he quotes two statements from my writings for the sake of demonstrating some contradiction between them.

To this I beg leave to oppose that, in fact, there does not exist any contradiction at all. By saying, "we state that we have not reduced the periodicity because of the coupling in parallel," I purposed only to declare that we absolutely have not *reduced* the periodicity, *as, indeed, there did not exist any necessity at all for us to reduce it.* I observed a periodicity of 42, or nearly so, in my dynamos at a time when the idea of running alternating machines parallel was as yet unknown, because the necessity of so coupling them was not recognised until after the introduction of the tranformer system. The experiments which we afterwards made with coupling in parallel showed that the periodicity above mentioned proved advantageous, among other things, *for the coupling in parallel* of my machines. Now, nothing was more natural for me than to preserve this periodicity, the other advantages of which were already well known to me from experiments dating from a period when Mr. Mordey's own work had not yet reached publicity.

As for our silence on the particulars of our alternate-current motor, we fully agree with Mr. Mordey's opinion, that "there are no doubt good and sufficient reasons for this reticence"!—Yours, &c., CHAS. ZIPERNOWSKI.

Budapest, Aug. 7, 1889.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you permit me to make a few remarks relating to Mr. Mordey's pioneer Paper and the discussion on the above subject? After reading through the Paper, discussion, and Mr. Mordey's reply as printed in the *Journal* of the Society of Electrical Engineers and Electricians, it seemed to me strange that at least some of the contested points should not have been settled in the minds of the members. But the theorists remained apparently unconvinced. Parental affection is very strong, and no doubt some members felt it too terrible to part so suddenly with their cherished offspring. No doubt, also, it is much easier to grasp the full meaning of the various speakers from their (presumably) recomposed remarks than when listening to them in succession, and I may, therefore, be whipping a dead horse in writing this letter, in which case I can only ask pardon for trespassing on your space.

In the absence of any statement from Mr. Mordey as to the strength of the current which passed between and through the armatures of the two machines when one was excited to 1,000 and the other to 2,000 volts, it appears safe to infer that it was not measured. We know, however, that the resistance and the self-induction of the armature were both very low (else how, indeed, could they have run together so perfectly?!) It thus appears that a "prodigious current" (to use the Presidenth expression) would be produced through the two armatures wit's but a comparatively trifling difference of E.M.F., and what was wanting in number of turns to produce demagnetisation of the poles would be amply made up by an enormous current.

As regards the objection made by Prof. S. P. Thompson and concurred with by Mr. Mordey at the time of his reply, *i.e.*, that the time ($\frac{1}{200}$ of a second) must be insufficient for a coil to take effect on the solid pole-piece, I think Prof. Thompson would not argue that the effect of the coil flying past at such a speed would be *nil? But*, the same cause which prevented the flying coil from instantly reducing the magnetisation to the value due to the component magnetising forces—self-induction, would also prevent the pole from recovering to its former strength before a second coil flies past and reduces the magnetisation a degree lower, and in this manner the pole strength will rapidly be reduced nearly to the value due to the compo-

Digitized by Google

nent magnetising force. In short, we have not to consider the effect of a single coil, but the cumulative effect of the whole, and I take it that the demagnetising force will be operating during a large proportion of the time.

Unless Mr. Mordey is able to state definitely that an unusually heavy current did not pass, I therefore think the President's explanation of the experiment is probably the true one.

It may be noted that this unusually heavy current (if it existed) might easily have escaped detection if unsuspected at the time of the experiment, especially if the conductors were large or the time of the experiment too short to allow of unusual heating; one reason being of course that the current through so small a resistance would not represent sufficient energy to show on the bands, another that the absence of even ring collectors in the Mordey alternator removes the possibility of a "splash" with even a prodigious current unless it were sufficient to fuse the conductor at some point.

Mr. Mordey charged the theorists with having neglected in their investigations the actions which take place in the field magnets. It appears to me that these actions will be very much more important in the case of machines with iron cores in their armatures than in those without. In the Mordey alternator and in others with no iron in the armatures the magnetic circuit in the fields remains uncharged except for the influence exerted by the current flowing in the armature coils. In the case of machines with iron in the armatures the field magnets are varying rapidly from "open" to nearly "closed" magnetic circuits, so that unless the field cores are nearly saturated when the magnetic circuit is "open," although self-induction will prevent the magnetisation of the poles from fluctuating between the two values which it would have if the field magnets were stationary in the two positions respectively, the field will be very unstable, and the machine consequently a bad regulator.

Mr. Mordey in his supplementary remarks describes a new alternator upon which I should like to say a word, and which I think bears upon Prof. Forbes' experience with a machine of similar design, *i.e.*, that it is almost a continuous-current machine.

In this machine the outside core bars are subject to no direct demagnetising influence when the magnet poles have passed them, but, on the other hand, have a splendid leakage circuit through the inside core bars, which are magnetised in the correct sense to assist the armature current in maintaining the magnetisation.

Now the demagnetisation of the outside bars is the vital point in the action of the machine, the magnetisation and demagnetisation of the inside core bars being practically without effect on the armature coil. It therefore appears that a greatly improved effect would be obtained by substituting for the single magnet a number of smaller magnets with alternately reversed poles, such as are more usually employed in alternators.

I trust we shall before long be favoured with Mr. Raworth's experimentally plotted curves of the currents in the Mordey alternator and transformer.—Yours, &c., W. B. SAYER.

Lisbon, 8th August, 1887.

MR. LANE-FOX AND THE ANGLO-AMERICAN BRUSH CORPORATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We enclose, at Mr. Lane-Fox's request, a copy of his remarks at the Brush Company's meeting to-day.

We may add that Mr. Lane-Fox has nominated Mr. Slade, Mr. Drake, and Mr. Gorham to carry on the negotiations on his behalf with the Brush Company.—Yours, &c.

DRAKE AND GORHAM.

2, Princes Mansions, Victoria-street, London, S.W.,
August 14th, 1889.

[COPY.]

I think it only right to mention that I have certain unsettled claims against the Brush Company.

The liquidation of the company make it imperative that these differences should now be dealt with, and I am afraid that unless we can come to an immediate understanding the whole question of my early connection with the Brush Company down to the present will have to be reconsidered.

I have done everything that was possible to get them settled amicably. Hitherto, however, I have allowed myself to be put off with vague assurances.

I should add that quite recently a very equitable proposal has been submitted to them on lines which, I understood from the manager, they were willing to agree to, but as I have not received from them any satisfactory assurance of a settlement I am compelled to refer to the matter at this meeting.

THE K.M.B. POCKET GALVANOMETER.

A combined detector galvanometer and ammeter has been brought out by Messrs. King, Mendham and Co., of Bristol. The galvanometer is made in two distinct parts. The front portion carries the needle and graduated dial, and is capable of rotation round its centre, its edge being milled to admit of easy movement; the back part contains the bobbins, which are wound to two measured resist-

FIG. 1.

ances. One half of the dial is graduated in degrees while the other portion represents an equally divided ampere, and the dial may be rotated so as to bring either half uppermost, the needle, of course, remaining in a vertical position. That part of the dial graduated in degrees is used uppermost when it is required merely to test a line wire or a battery, as with an ordinary detector galvanometer. The

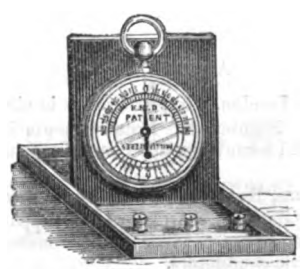

FIG. 2.

other portion of the dial is used uppermost when it is desired to find the strength of the current, which is indicated in milliamperes. In Fig. 1 the instrument is shown with its two graduations, that part divided into degrees being uppermost. Galvanometers are also supplied in cases, as shown in Fig. 2. This is so arranged that the vertical portion against which the instrument is fixed is removable,

FIG. 3.

and fits down into the tray, which gives it the protection it requires; the galvanometer can thus be carried in the tool bag without fear of being damaged. Another method adopted for mounting the galvanometer is represented in Fig. 3, and so mounted it can be used as a laboratory galvanometer.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

July 30, 1889.

12,046. F. MARQUARD. London. Improved composition adapted to electric insulators and other articles and uses in the arts and manufactures.

12,047. The Hon. F. D. LEIGH. London. A mode of rendering the knobs or buttons of electric bells, electric switches, and suchlike luminous in the dark.

12,066. T. W. WATSON and A. H. WATSON. London. An electric hand signalling lamp.

12,082. A. J. JARMAN. London. Improvements in the arrangement and regulation of electric motors for traction, marine propulsion, and suchlike purposes.

July 31, 1889.

12,135. W. E. HEYS. Manchester. Improvements in electric cut-outs, and apparatus for opening electric circuits (N. Chaize and J. Chaize, France).

12,145. P. M. JUSTICE. London. Improvements in generating electricity or magnetism by the application of heat (E. G. Acheson, United States).

12,153. G. BROOK. Huddersfield. A new or improved application of electric call-bells or gongs to tables or other articles of furniture in hotels, refreshment rooms, and similar places of refreshment or amusement.

12,161. J. J. PERKINS. Spitalfields. Electric alarm rug or mat.

12,185. A. H. HOWARD. London. An improved mode of distributing electricity.

12,188. H. H. LAKE. London. Improvements in apparatus for regulating and utilising electric currents (F. V. Maquaire, France).

August 1, 1889.

12,236. J. SWINBURNE. Wimbledon. Improvements in appliances for the generation, distribution, measurement, and use of alternating or commutated electric currents.

12,237. J. SWINBURNE. Wimbledon. Improvements in and connected with electric transformers.

August 2, 1889.

12,251. J. A. TIMMIS. London. Improvements in electric couplers.

12,270. H. J. PEDDIE. Edinburgh. Improvements in apparatus for electrical sight and sound signalling on railways and in mines and coal-pits.

12,286. Sir C. S. FORBES, Bart. London. An electric current meter.

12,313. H. LEA. London. Improvements in apparatus for regulating and maintaining constant or nearly constant the electromotive force in electric conductors.

12,331. F. KING and W. P. MENDHAM. Bristol. Improvements in self-adjusting electric pendulum indicators.

SPECIFICATIONS PUBLISHED.

1888.

12,832. ANDERSEN. Dynamo electric machines. (Price 8d.)

12,963. ZIGANG. Telephone. (Price 8d.)

COMPANIES' MEETINGS & REPORTS.

Anglo-American Brush Electric Light Corporation (Limited).

An adjourned extraordinary general meeting of the shareholders of the Anglo-American Brush Electric Light Corporation (Limited) was held at the office of the Corporation, 112, Belvedere-road, Lambeth, on Wednesday last, under the presidency of Mr. J. S. Sellon, in the unavoidable absence of Lord Thurlow.

The CHAIRMAN briefly explained that the meeting was called merely to confirm the resolutions passed at the extraordinary general meeting held on the 26th of July, fully reported in *The Electrician* of that date.

The resolutions referred to were then put *seriatim* and unanimously confirmed.

[For the resolutions which this meeting was called to confirm see *The Electrician*, August 2, 1889, p. 339.]

City of London and Southwark Subway Company.

The tenth ordinary general meeting of the proprietors of this Company was held at Winchester House, Old Broad-street, E.C., on Tuesday last, for the purpose of receiving the report of the Directors and statement of accounts for the half-year ended June 30th, 1889, and the transaction of the ordinary business of the Company. Mr. C. Grey Mott, the Chairman of the Company, presided.

Mr. H. H. M. SMITH, the secretary, read the notice calling the meeting.

The report of the Directors (which was taken as read) stated—"The boiler-house at the Stockwell depôt is approaching completion, and the boilers are being placed in position. The other works at this depôt in connection with the electric supply, the hydraulic power for working the lifts, the carriage sheds and workshops, are also making good progress."

The CHAIRMAN, in moving the adoption of the report, said that since the date of their last meeting they had carried out some very important works without any serious accident whatever, and at the present time the whole of the tunnelling, with the exception of a short piece between the Oval and Stockwell, where they had met with a bed of wet gravel, had been completed. The underground works at three of their stations had been

finished, and at the three others were in course of completion ; the surface stations at Great Dover-street and Elephant and Castle had also been finished, and the alterations at the City station at King William-street were being pushed forward. The engines and carriages for the experimental trial were in the tunnel now, and they hoped that in the course of a very short time, the first trial (which would be on behalf of the contractors) would take place. After that the actual preliminary trial would be made. They had, as the shareholders knew, acquired a fine piece of land at Stockwell, the terminus of the line, upon which they were erecting the needful buildings and were also putting up the machinery for working the electrical plant to give the motive-power, and also the machinery for the hydraulic lifts. The whole of the machinery would be completed and ready by the time they had got through the wet gravel, which work was slowly progressing. The rails were laid for the full length in one tunnel and for a great part of the distance in the other. When he met the shareholders six months ago he expressed the hope that at this meeting he would be able to announce either that the line was open for traffic or else to fix the date when that opening would take place, and he could assure them that no one regretted more than he and his colleagues did that any further delay should have taken place ; but it had to be borne in mind that theirs was an entirely novel undertaking in every respect, not only as regarded construction, but also motive-power. The results achieved, he thought, reflected the greatest credit on the contractors, engineers, and all concerned. Since the date of the last meeting they had raised additional capital to the extent of £75,000, which they believed would be ample. They had not done this by public advertisement, but by arrangement with financial houses in the City ; this had, of course, entailed expenses in the way of commission and concessions in price, but they had saved the advertising bill. They had pushed forward the line as rapidly as possible, and they trusted that they would within a very short space of time be in a position to open it throughout from the City to Stockwell. Everything had been done in such a way as to render failure, when the opening was accomplished, practically impossible. He formally moved the adoption of the report and accounts.

Mr. A. HUBBARD seconded.

The CHAIRMAN invited discussion.

After remarks from Messrs. Elwood, Russell and Rendell,

The CHAIRMAN stated that it was originally intended that the line should only be constructed to the Elephant and Castle, but afterwards, when the extension to Stockwell was decided upon, they determined on having their terminal station there, and the electrical plant for working the locomotives also located there. Having regard to the fact that as the whole line will within a very short space of time be completed, they did not intend to go to the expense of making the Oval a temporary terminal station. He said that the fresh capital of £75,000 to which he had alluded would rank *pari passu* with the existing capital. Although he could not fix the exact date of opening, he believed it would be within a reasonable time—a few months.

The resolution was put and carried.

There being no further business to transact a vote of thanks was accorded to the Chairman, and the meeting separated.

NEW COMPANIES REGISTERED.

THE BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—Registered by Renshaws, 2, Suffolk-lane, E.C., with a capital of £750,000, in 150,000 Preference Shares of £2 and 150,000 Ordinary Shares of £3 each. Object, to acquire by transfer (for the purpose of reconstituting the Anglo-American Brush Electric Light Corporation, Limited) the undertaking and business heretofore carried on by the Anglo-American Brush Electric Light Corporation (Limited), in the United Kingdom and elsewhere, and also the letters patent and patent rights, and the lands, buildings, and other hereditaments, works and conveniences, and fixed and movable plant held, occupied and used by the Anglo-American Brush Electric Light Corporation (Limited), and stock-in-trade and effects and all other the property of the corporation ; and to undertake and satisfy the contracts and any portion of the liabilities and obligations of the corporation which may not be satisfied by the corporation or the liquidators thereof ; and with a view to such reconstitution to enter into an agreement to be made between the Anglo-American Brush Electric Light Corporation (Limited), and J. B. Braithwaite, jun., and Emile Garcke, the proposed liquidators of such corporation of the one part, and this company of the other part, and to carry the same into effect ; to continue this business, and further to acquire the undertaking and business of the Falcon Engine and Car Works (Limited), heretofore carried on by the company at Loughborough, and the stock-in-trade, effects and other property of that company, and with a view thereto to adopt an agreement dated July 12, made between the Falcon Engine and Car Works (Limited) of the one part, and Bertrand Broadhurst, as trustee for this company, of the other part, to carry the same into effect ; to carry on the businesses of electricians, mechanical engineers and manufacturers of any kind of electrical apparatus and appliances, and workers and dealers in the same. The first subscribers are :—

	Shares. Ord.	Pref.
Lord Thurlow, 33, Chesham-place, S.W.	1	1
J. S. Sellon, 78, Hatton-garden	1	1
E. Garcke, 112, Belvedere-road, Lambeth, S.E.	1	1
Col. F. G. Stewart, 16, St. James'-square, S.W.	1	1
E. Cooper, 14, George-street, Mansion House, E.C.	1	1
E. Woods, 45, Onslow-gardens, S.W.	1	1
J. Raworth, 112, Belvedere-road, Lambeth	1	1

There shall not be less than five nor more than nine directors. The first are the Right Hon. Lord Thurlow, J. S. Sellon, Colonel F. G. Stewart, E. Woods, J. B. Braithwaite, jun., the Duke of Marlborough, and A. H. Sanderson. Qualification, £500. Remuneration, £2,000, divisible. When in any year the dividend, with bonus, if any, on the Ordinary Shares shall amount to more than 10 per cent. on the capital for the time being called up, the directors shall be entitled to an additional sum equal to one-tenth of the amount of such dividend, provided that such additional sum shall not exceed in any year £10,000.

COLUMN PRINTING TELEGRAPH SYNDICATE (LIMITED).—Registered by Rollit and Sons, 12, Mark-lane, E.C., with a capital of £10,000 in £50 shares. Object, to acquire certain patents and rights in relation to printing telegraph machines, and with a view thereto to adopt an agreement, dated August 1, made between J. Moore and J. E. Wright, of the one part, and J. E. Crockett, on behalf of the Syndicate, of the other part. Most of the regulations of Table A apply.

THE FOWLER-WARING CABLES COMPANY (LIMITED).—This company, of which the capital is £200,000 in 40,000 shares of £5 each, 300 being Founders' Shares, has been formed to acquire and unite the electric cables business now carried on by John Fowler and Co., Leeds (Limited), and by Mr. Richard Waring, 85, Queen-street, London ; and to acquire and work the patents taken out for the United Kingdom by Mr. James Tatham, of Philadelphia, U.S.A., and by Mr. R. W. Eddi on, of the Steam Plough Works, Leeds, and by Mr. R. S. Waring, of Pittsburgh, U.S.A., for improvements in the manufacture and insulation of metal-covered electrical cables. Further particulars will be found on page v. of our advertisement pages.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended August 9, 1889, amounted to £5,176.

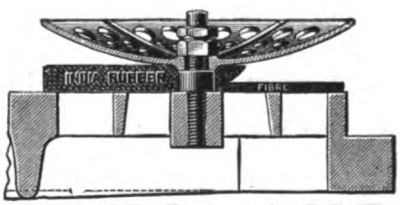
WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the month ended 31st July, 1889, amounted to £5,350.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended August 9, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,631.

PERSONAL.—Mr. H. A. Henderson informs us that he has opened a practice at 20, York-chambers, Brazenose-street, Manchester, as consulting electrician and electrical engineer.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Johnson & Phillips.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster. MANVILLE & MADGEN, *Managing Directors.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 588.—Vol. XXIII. FRIDAY, AUGUST 23, 1889. Price Fourpence.

NOTES.

On another page will be found the last of the long-expected Board of Trade rules for the erection of overhead wires. It must be understood, however, that these rules are not of universal application, but will only be enforced in those cases to which the Board may think proper to apply them. Moreover, they are not intended to apply to Telegraph or Telephone lines, but solely to lines used for the purpose of conveying electrical energy. It will be remembered that, by the courtesy of the Board, the Committee of the Electrical Section of the Chamber of Commerce were enabled to see the original draft, and on their suggestion one or two slight modifications, chiefly in the insulation clauses, have since been made. As the rules now stand we do not think that any reasonable objection can be taken to them.

The Committee of the Paris International Electrical Congress of 1889, whose first sitting takes place to-morrow (Saturday), has issued a set of "Reports" on various subjects with which it is proposed that the Congress shall deal. These reports have been severally drawn up by various individual members of the Committee, and consequently they vary somewhat in the method of treatment and in value. The first report, by M. Pellat, is on Electrical Standards, and gives a brief but useful *resumé* of the present state of the subject, describing the existing standards, and giving the results of the latest determinations of their value. Next we have a report, by M. Potier, on the Measurement of Energy, chiefly in reference to the determination of the efficiency of dynamos. After referring to the Hopkinson and Ravenshaw methods, he describes an important improvement, due to M. Fontaine, which will be new to most of our readers. A translation of this Paper will be found in another column. The report of M. Touanne, on Telephony, is also translated in this issue. In M. Picou's report, on Transformers, he gives a *resumé* of the history of the subject which is quite unbiassed; the general treatment is, however, highly scholastic, and we find very little which would specially interest practical men. M. Hillairet's report on Dynamo Machinery is wholly historical, and even then the writer confines himself chiefly to the development of theory rather than of practice. The report concludes with some remarks on methods of distribution, the transmission of power, and the use of the dynamo in electrolysis. This is a rather disappointing performance. Next we have a report by M. Hippolyte Fontaine on Electric Lighting, in which the author claims for France the honour of having been the cradle of the industry, several permanent installations having been at work as long ago as 1874. M. Fontaine's report deals in succession with each type of lamp, and he then very briefly discusses Central Station Lighting under the three heads of Continuous-Current Stations, Battery Stations, and Alternate-Current Stations. Lastly, we have a report from M. D'Arsonval on Electro-Physiology, which is no doubt a competent and reliable summary of the present state of knowledge on this obscure subject.

After going carefully through these reports we are at a loss to understand what particular purpose they can be supposed to serve, unless they are to be taken as a basis of discussion at the meeting of the Congress. Even so, it seems to us that the distinguished authors would have done better service had they prepared Papers upon some particular question of importance. Excellent as these little essays are as a whole, they deal too much in platitudes and generalities, and are altogether too much like schoolboy themes to meet our English tastes.

The proposed scheme for establishing a Government Standardising Laboratory seems to have been imperfectly understood by certain sections of the electrical trades, and it may be hoped that the circular letter addressed to them on the subject, and printed in another column, will have the effect of extracting further information on which the Treasury may be induced to act. We are informed that delay has arisen in consequence of that Department not being satisfied with the case as presented to it by the Board of Trade. It should be the business of the Chamber of Commerce to supply the last-named Department with ample material for making good its recommendations.

The perusal of Dr. Lodge's remarkable book on Modern Views of Electricity (which we review in another column of this issue) almost inevitably leads one to give the reins to imagination and to endeavour to forecast the possibilities which the future may have in store for the electrical engineer. But resisting that temptation, we wish rather to insist upon the fact that no electrician who means to keep up with the running can afford to neglect these theoretical developments merely because at present they are theoretical only. It would seem probable, however, that the first practical service which will be rendered by modern modes of conceiving electrical phenomena will be not so much in the direction of brilliant and start-

Digitized by Google

ling invention as in a clearer and more accurate perception of the nature of the problems to be dealt with; although this must inevitably lead, in turn, to improvements in practice, perhaps of a radical character. It is, we take it, rather more likely than not that the fact of the transfer of energy taking place wholly in the dielectric may in time become one of our habitual, and perhaps even one of our most useful, concepts. It is not so many years since FARADAY'S conception of "lines of force" was exclusively the property of a few theorists, whereas now it dominates the mode of thought and of expression of every practical worker in electro-dynamics. As to the nature and actual extent of the changes, which from our present standpoint may be dimly discerned as possibilities of the future, we shall not at present hazard even a surmise; but it is very difficult to suppose that the full recognition of these modern views—the knowledge of the facts of electrical radiation, of the electro-magnetic theory of light, of the fact that the transference of energy is confined to the dielectric, and, to mention only one thing beside, the continuous approximation towards a rational theory of the ether and its functions—are all destined to remain entirely without direct influence upon our practical work. How long a time may pass, however, before this knowledge is brought to bear is a matter which must chiefly rest with electrical engineers themselves. Meanwhile we once more counsel them not to neglect developments of theory merely because they are unable to see any immediately practical application.

WITHOUT anticipating Mr. MORDEY'S reply to Mr. ATKINSON, there is one remark which we feel it necessary to make. Mr. ATKINSON correctly points out that when running at normal speed the Mordey Alternator very closely fulfils the conditions demanded by the HOPKINSON formula for successful working in parallel. But our correspondent has overlooked the fact that the bottom is entirely knocked out of this argument by the announcement which we made in our last issue that *these alternators will run synchronously at any speed.* It is hardly necessary to add that there can only be one speed which suits Dr. HOPKINSON'S formula, at least—to allow for variations of L—at the same excitation. The circumstance mentioned by our correspondent is therefore reduced to the level of a curious coincidence. We understand that it is Mr. MORDEY'S intention shortly to invite a number of electricians to witness this experiment.

WE have received a long and interesting letter from Mr. SWINBURNE, but unfortunately it came to hand too late for insertion in the present issue.

AT the Stevens' Institute of Technology (U.S.), Messrs. SEARING and HOFFMAN have recently determined the curve representing the variation of the E.M.F. in the armature of a WESTINGHOUSE alternator. This is, we believe, the first time that this curve has been experimentally obtained for an alternator with iron in the armature. It is satisfactory to know that the actual curve differs very little indeed from a true sinusoid. The small divergence which actually exists is such as to make the curve a trifle steeper at the first rise and a little flatter at the top. The agreement is, however, sufficiently close to be almost, if not quite, surprising. The experiments were made by means of a condenser charged from a projecting point on the armature shaft, which was set to strike against a fixed stud. The point was made of somewhat flexible steel wire, and could be accurately adjusted at any required angular position. The stud had a curved surface, and was pressed outward by a weak spiral spring, so as to make the contact as brief as possible. Every precaution seems to have been taken to ensure accuracy.

A PAMPHLET has been issued by the Electric Power Storage Company containing a description of their system of distribution with accumulator sub-stations, which we commend to the attention of everyone interested in central-station work. Nearly two years ago we had the pleasure of examining the working of the automatic appliances which form a prominent feature of this system, and although we understand that improvements in detail have since been effected, we were struck both by the simplicity and the ingenuity of the devices employed. Unlike some other attempts which have been made to employ automatic methods of manipulating the batteries, nothing serious can occur even should the mechanism on occasion fail to act. The company claims that the coal consumption does not exceed 9 to 10·5lbs. per Board of Trade unit invoiced to the consumer, and that the total cost including maintenance and depreciation is only 3·26d. per unit. We shall be sincerely glad to learn in due time that the experience of the Chelsea Company bears out this sanguine estimate. Nothing could be better for the electrical industries than a conclusive demonstration of the fact that secondary batteries had become a commercial success both for central-station lighting and for traction. Such conclusive demonstration is not yet available, though we trust it will not be much longer delayed.

There is one statement made by the Electric Power Storage Company in their very reasonable desire to discredit the alternating system which admits, we think, of a very simple explanation. We quote the passage *verbatim*:—

"Reference to the proceedings of the Institution of Electrical Engineers, Volume XVIII., p. 251, will show that at Brighton, where in the Central Station the system has been altered from the old 'Brush' machines working a 'Multiple Series System' of supply, using *24lbs. of coal* per Board of Trade unit, to the more modern arrangements of the Alternating System, using Lowrie Hall Converters and Elwell-Parker alternating dynamos, *the coal consumption is 25lbs.* per Board of Trade unit. This large consumption of coal is mainly due to the comparatively large amount of energy required by the primary circuit of alternating transformers when the secondary circuits are not being used at nearly the maximum capacity, a condition of affairs which must last about 20 hours in every day."

But we believe the truth to be simply this: that whereas with the multiple-series system the day service was performed by one machine of small size, in the second case a machine, if we remember correctly, of 100 horse-power was kept running all day. It is, of course, open to further question whether either the dynamo or the transformers were in this

Digitized by Google

case the most economical specimens of their class. We should like to see the figures from other alternating stations showing the work done in the primaries when running light during the day time.

THE notion that an increase of energy can be obtained from the secondary coil of a transformer by merely applying a continuous source of heat to the iron core is so utterly opposed to our usual ideas that one's first inclination is to dismiss the matter without a second thought. But whilst we cannot help believing that the notion rests upon some erroneous observation, yet the fact that it is being persistently asserted by Mr. ACHESON—who is held in the United States to be an accomplished electrician—seems to make it worthy of mention. Mr. ACHESON'S experiment is described more fully on another page. We hope some one of our readers will repeat it, and let us know the result.

VOLUME I. of "The Alternate Current Transformer, in Theory and Practice," by Dr. J. A. FLEMING, is now ready. This first volume is entitled, "The Induction of Electric Currents," and deals wholly with the theory, and it therefore covers ground which has never hitherto been systematically treated in a manner calculated to be of immediate use both to the student and to the practical worker in electro-dynamics. About one-half of the chapters forming the present volume have already appeared in these pages in serial form, so that our readers will be to some extent acquainted with the general style and scope of the present volume. In a few months we hope to commence the publication in the same form of selected chapters from the second volume, which will probably be entitled "The Transformer in Practice." The price of Vol. I. is 7s. 6d., post free 8s. 0d. It is published at *The Electrician* office.

A Destructive Lightning Flash.—At Marnhull in Dorsetshire 18 sheep, which had sought shelter under a tree from a storm, were recently killed by a flash of lightning.

The Fowler-Waring Cable Company.—This company has, we understand, decided to erect large works on the Thames, below London Bridge, for the manufacture of their cables.

Telegraphic Money Orders.—The Postmaster-General promises that the scheme for telegraphic money orders will be introduced by way of experiment at certain offices on Monday, 2nd September.

Poole.—The Poole Town Council have given their consent to the application for a Provisional Order by the Anglo-American Brush Corporation and by the Electric Construction and Maintenance Company.

Haslingdon.—At the last meeting of the Haslingdon Local Board it was decided that the assent of the Board should not be given to the application of the Municipal Electric Light and Power Corporation.

The Priestman Oil Engine.—The Priestman oil engine, of eight horse-power, has just been adopted at the Bwllfa and Merthyr Dare Collieries in South Wales for pumping, where it is working well and giving great satisfaction.

Postal Telegraph Revenue.—The total receipts from the Telegraph Service paid into the Exchequer from April 1st to August 17th of the present year amounted to £815,000 against £740,000 for the corresponding period of 1888.

Sale by Auction.—It will be seen by our advertisement columns that Messrs. Wheatley Kirk, Price and Goulty are instructed to sell by public auction, early next month, the business, patent rights, plant, and stock-in-trade of the Jensen Electric Bell and Signal Company.

Electric Tramcars for Birmingham.—Arrangements are satisfactorily progressing for the introduction of electric tramcars in Birmingham, on the Bristol-road route, the relaying of which is nearly completed. The cars to be used will be of the Julien type, and the work is being carried out by Elwell-Parker.

The Eiffel Tower Struck by Lightning.—During a great storm which passed over Paris on Monday evening last, a flash of lightning struck the Eiffel Tower. No damage of importance was done, although all those who were on the structure at the time felt a tremendous shock, and some of the metal work was fused.

The Electric Lighting of Penarth Dock.—At the last Board meeting of the Taff Vale Railway directors, tenders were considered for lighting Penarth Dock by electricity. It was decided to carry out the work at once, and it has been entrusted to Messrs. J. B. Saunders and Co., electrical engineers, at Cardiff.

The Georgetown Telephone Exchange.—According to the report of the Postmaster-General of British Guiana, Mr. Samuel Vyle appears to have been very energetic in getting the Georgetown Telephone Exchange into good working order, and the result is that the calls have increased by 100 per cent. in one year.

Chester.—At the quarterly meeting of the Chester Town Council last week, a recommendation of the Watch Committee was agreed to, that application be made to the Board of Trade for a Provisional Order authorising the Council to supply electricity within the city, and that a special meeting be called to discuss the question.

Keswick.—For some time past the workmen have been employed in wiring the building where the electric light is to be used. Progress is also being made by Messrs. Johnson and Phillips with the work connected with the erection of the central station at Forge, and it is still expected that the 1st October will see the light first in use in Keswick.

Fleetwood.—At a meeting of the Fleetwood Improvement Commissioners last week, it was decided that application should be made to the Board of Trade for a Provisional Order empowering the Commissioners to supply electricity for public and private purposes within the district. The Commissioners intend to oppose the application of the National Electric Supply Company.

Extension of Electrical Works.—Messrs. C. A. Parsons and Co., who are at present carrying on business at the works in Park-road, Gateshead-on-Tyne, are building extensive new manufactories on the opposite side of the River Tyne at Heaton, Newcastle, to which their business in the manufacture of all descriptions of electrical machinery will be removed in about two months time.

Launceston.—At Monday's meeting of the Town Council, a communication was received from the Devon and Cornwall Electricity Supply Company asking for the consent of the Corporation to an application to the Board of Trade for a Provisional Order authorising the supply of electricity for public and private purposes within the Urban Sanitary area. Sanction was readily granted.

Troops on the March Struck by Lightning.—Last week, as a detachment of Lancers, consisting of a corporal and four men, was returning from the manœuvres at Spandau, a flash of lightning struck a tree close to them and glanced off into the middle of the troop. All riders and horses were hurled to the ground. The corporal and his horse were killed on the spot, and one of the troopers was paralysed for some time after.

Salford.—A special meeting of the Salford Council will be held on the 20th of September to consider the notice given by the Manchester House-to-House Electricity Company, and to consider the proceedings of the General Purposes Committee and the Parliamentary Sub-Committee, with a view of applying to the Board of Trade for a Provisional Order to authorise the Corporation to supply electricity within the area of the county borough.

Digitized by Google

The Paris Municipal Central Station.—At the last meeting of the Conseil Municipal the purchase of measuring instruments and accumulators for the testing-room of the central station was authorised, the amount to be spent not to exceed 6,700fr. Tenders were also accepted for arc lamps (65,000fr.), for steam pipes and distributing boards (15,500fr.), and one from M. Patin for transformers (30,700fr.), having a total capacity of 226 kilowatts.

The School of Electrical Engineering.—We have great pleasure in drawing attention to this admirable institute in Hanover-square, W., the autumn session of which will shortly commence. Efforts have been made to overcome the chief defects of technical schools of this class by providing it with plant and the appliances of a workshop, two-thirds of the time of every student being spent in practical work. The examiner is Mr. Gisbert Kapp.

Calcutta.—Messrs. Octavius Steel and Co., Calcutta, acting in conjunction with Messrs. Crompton and Co., have, says *Indian Engineering*, obtained sanction for a scheme for lighting a portion of Calcutta by electricity. They propose beginning with the Strand-road from Chitpore to the jetty opposite the Bank of Bengal, including the Hooghly-bridge, jetties, Port Commissioners' Buildings, and wharves along the river face. The scheme is expected to be in full work within a year.

Eastbourne.—At the last meeting of the Eastbourne Town Council, a memorial was read from the inhabitants of Kilburn-terrace, Junction-road, complaining of the nuisance caused by the smoke and smell from the Electric Light Company's works, the nuisance arising, it was said, in consequence of acids being used to clean the boilers. Several members of the Corporation said the smell was seriously injuring the town, as it was attributed by visitors to bad drains. It was decided that notice should be given the company to discontinue the nuisance.

Southampton: Important Decision.—With reference to the application of the Town Council for sanction to borrow £1,440 for purposes of electric lighting, the Local Government Board have written that they have submitted a case to the law officers of the Crown on the question whether local authorities were empowered to manufacture electricity for lighting of streets, markets and public buildings in their district without obtaining a license or Provisional Order under the Electric Lighting Acts. Their opinion was that a Provisional Order must be obtained.

Dundee University College.—The seventh session of this college commences next month, with a varied and liberal programme. Based on the lines of the Manchester Victoria University, and with a somewhat similar history, the Dundee University is one of the best of its kind in North Britain. Its Calendar for 1889-90, which we have just received, is well worth the shilling charged for it even to students who are not within reach of the college, its examination papers for last year being printed in full, together with some very useful information as to the requirements of the leading competitive examinations.

"Electrical Plant" Exhibition Supplement.—Our esteemed contemporary, *Electrical Plant*, has issued this week the first of a series of three supplements in connection with the Birmingham Exhibition. The first number contains a detailed account of the engines and boilers, the coal pit ("specially written by the wild-eyed office poet"), and the exhibits of Messrs. Crompton and Co., and of Messrs. Laing, Wharton and Down. We must congratulate our enterprising contemporary on its first supplement, which, in addition to possessing some technical value, contains a good deal of "excellent fooling" in a style it has made peculiarly its own.

The Proposed Electric Railway at Eastbourne.—The meeting convened by the Mayor to consider the question of a proposed electric railway along the sea-front, from the Wish Tower to Beachy Head, was held in the Eastbourne Town Hall on Monday evening last. Only some 20 persons attended. The Mayor having alluded to the very small attendance, proceeded to say that the Duke of Devonshire, who owned the land along which the proposed railway would pass to Beachy Head, would oppose it at every step, and many of the residents would also oppose the scheme. As no one seconded a motion in favour of the proposed line to Beachy Head, the meeting closed with votes of thanks to the Mayor.

Mr. Edison in Paris.—Mr. Edison was present at the meeting of the Académie des Sciences on Monday last. He was introduced by M. Janssen. The President, M. des Cloiseaux, welcomed the great electrician in a very cordial speech, which M. Janssen translated into English. A perfected phonograph is to be presented to the Académie des Sciences by Mr. Edison, and provided with a sufficient number of cylinders to enable it to preserve a record of the utterances of its members. On Wednesday evening Mr. Edison had a dinner given to him by the Société Générale des Téléphones. Illustrations were given of the phonograph and the telephone, the latter being placed in communication with the Opera and the Opéra Comique.

St. Thomas Charterhouse Boys' School.—We are glad to hear that the results of the recent Science and Art Examinations show that the pupils of this school have again achieved a remarkable success. Every boy—fifty-eight in number—in the upper class was presented for examination, and of these none were completely unsuccessful, a large number passed in four subjects, and several passed in six. At the City and Guilds Technical College late Matriculation Examination the whole of the candidates from this school succeeded in qualifying for admission. It is with great regret, therefore, that we learn that, owing to the lowness of the fees, the committee are put to great straits to continue this school, which is perhaps the only school in London giving technical instruction for the benefit of the upper section of the working classes.

The Telegraph on the East Coast of Africa.—The Portuguese journal *O Diario Popular* refers, in its issue of the 9th August, to the rapid development of the telegraph system in Mozambique. It states that Quillimane will shortly be in communication with Inhamissengo, Sena and Tete. The two first sections are already finished, and the third section to the interior town of Tete is expected to be completed shortly. The delay is attributed to the difficulty in obtaining workmen sufficiently skilled to undertake the work. The same journal also says that telegraphic communication between the two banks of the Zambesi by cable is about to be established. Preparations for a line between Sena and Chupanga are likewise in a forward state. Much of the success of these undertakings is due to the energy and enterprise of Senhor Alferes de Andrade, who has had the work in hand.

The Proposed Government Standardising Laboratory.—The following letter on the subject of the recent circular relating to the proposed Standardising Laboratory, has been sent out by the London Chamber of Commerce:—

"Sir: As there appears to be some misunderstanding on the subject of the recent circular sent out by this Chamber respecting the proposed Government Standardising Laboratory, at the suggestion of Mr. Crompton, chairmain of the section, I beg to call your attention to the following facts:—I have called on several of the leading instrument makers and asked them their opinion as to the value of the Kew certificates. I am informed that whereas the fee for examining thermometers, barometers and sextants is very small, that is to say averaging between the limits of 1s. and 2s. 6d., the instruments carrying these certificates command from 20 to 25 per cent. higher prices. The watch certificates are given to a comparatively small extent, but similarly their value becomes enhanced to an extent far exceeding the amount of the fees. It appears further to be admitted that the laboratories established by foreign countries at Berlin and Paris are used to a considerable extent for the certification of voltmeters and ammeters, in addition to the principal work of testing house-meters. These certificated instruments command a better price than those which are sold merely on the maker's reputation. The British trade is placed at a disadvantage on the foreign market as foreign-made instruments with such certificates are preferred to English instruments without them. I also wish to call your attention to the fact that all instruments used under the Electric Lighting Acts will have to be certified, and it is obvious that the purchaser of such instruments will prefer to buy them of a maker of such certified instruments rather than take the trouble of getting them certified himself. Should the above facts cause you to modify your views, I should be glad if you will send in another return of the probable number of instruments you are likely to send in for certification. The returns of house-meters, which have already been received from five sources only, amount to nearly 17,000 per annum."

THE PARIS EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT).

The Exhibit of MM. Alioth et Cie.

MM. R. Alioth et Cie. have a well-arranged exhibit in the Palais des Machines, showing various types and sizes of the "Helvetia" dynamo and the methods of construction adopted by the Company, together with their newest forms of arc lamps, instruments, &c. The dynamos are arranged in two rows in descending sizes on either side of the stand; a large shunt machine and five compound ones occupy one side, and are driven off the main shafting, while a large series machine and four smaller ones are on the other side, and driven from a vertical engine in the corner of the stand

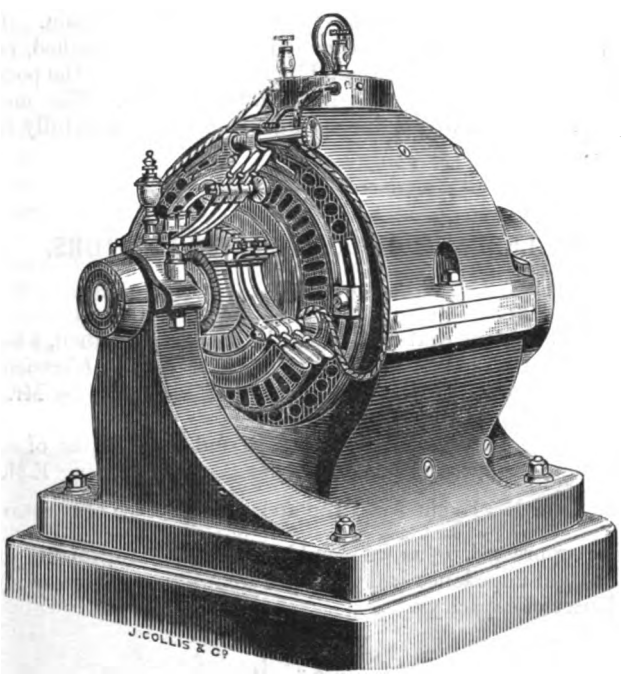

FIG. 1.—Helvetia Dynamo.

The general construction of the series and shunt machines will be understood from Fig. 1. The circular frame forms part of the magnetic circuit, and the small amount of leakage oft he lines of force is a special feature. All the machines have four poles fixed inside by large screws, the heads of which will be noticed on the outside of the frame, indicating the positions of

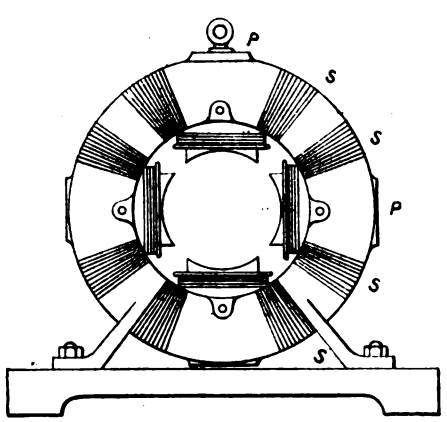

FIG. 2.—"Helvetia" Compound-wound Dynamo, showing Method of Winding the Shunt and Series Coils.

the poles. The framework usually consists of two castings, except in the case of the largest machines, where the plummer blocks and bedplate form a third casting. The same circular form is employed in the compound machines shown in Fig. 2. The field-magnet frame or body of the dynamo is in four pieces, however, the joints being in the horizontal and vertical lines passing through the centre of the circle, and the bolts concealed by the wooden panels (P, Fig. 2), to which the terminals, &c., can be fixed. The outward appearance is that of a solid ring, of oval section. The series or main coils are wound on the four pole pieces and the shunt coils, S, in eight sections round the frame. The armatures are built up of insulated rings in the usual way, except that the latter are arranged in groups of from 6 to 12, with gaps nearly $\frac{1}{8}$in. wide between them to allow of good ventilation. The coils are wound in segments first, and then fixed in position; the form of these is shown in Fig. 3. They may consist of one or more turns, according to the volts required from the machine, and are flattened and twisted at the ends, as shown at *a*, Fig. 3. Any one of the segments can be removed in case of bad insulation without unwinding the others. Slight gaps are also left between the coils as well as between the rings above mentioned, so that the air circulates right through the armature, causing excellent ventilation, and allowing in the fine wires a current density of six amperes per square millimetre (3,870 amperes per square inch) without over-heating. The bearings for the armature are carried by separate castings bolted on to the framework of the machine.

FIG 3.

The brush-holders, in the form of machine shown in Fig. 1, are fixed to a circular frame working in guides and controlled by a screw or hand wheel, so that both brushes may be moved together to shift the lead. The compound machines are fitted with the form shown in Fig. 4. A brass sleeve is clamped to the holder H, which is fixed to the framework; on to this are fastened the holder itself, B, and the rod R, which are both separate, and can be fixed relatively in any position, according to whether the brush is above or at the side of the commutator. The weight W is fixed at any point on the rod R that may be needed to counterbalance the weight of B. By raising the lever L the brush falls forward on to the commutator. In every case wire gauze folded up to the required thickness is used for the brushes instead of the usual copper strips.

In the centre of the stand are two small machines, one running as a generator and the other as a motor. This arrangement is to exhibit a motor speed-regulator which is shown in action, the generator driven by the motor being usually employed to light a projector set up in the middle of the table. This regulator consists of a set of resistance coils thrown in and out of the main circuit by a sliding contact running on a long square-threaded screw with a large cogwheel at one end and gearing with a small wheel on a spindle placed above it. This

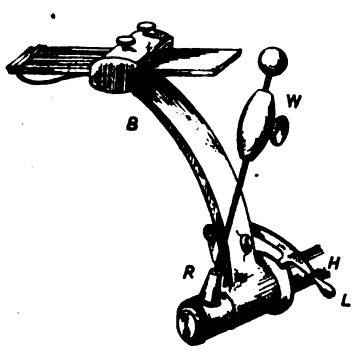

FIG. 4.—Brush-holde of the "Helvetia" Compound-wound Dynamo.

spindle carries two friction cones under the control of a governor, by the action of which they are respectively thrown into contact with two bevel wheels driven in opposite directions by a third wheel, which is in its turn driven by the motor. If the speed is too high, one of these wheels is thrown into contact with its friction cone, and the spindle is turned in one direc-

Digitized by Google

tion, thereby throwing in resistance; if, on the other hand, the speed is too low, an opposite action takes place due to the spindle being turned in the other direction by the second friction cone. The governor itself consists of a solid ring set on angle and controlled by a spring of suitable strength.

The arc lamp made and exhibited by the company is shown in Fig. 5. There are three coils in the regulating mechanism; the upper coil on the left may be described as the break-coil, and is part of the electro-magnet which generates eddy currents in the disc D and controls the movements of the large wheel W. The lamp is differential in its action. The fine coil S, which is a shunt across the carbons, and the main coil M are placed vertically one above the other. The current entering at the terminal T_1 passes through the break-coil B, thence to the carbons, and through the main coil M to the other terminal T_2. The bobbin of the coils M and S is hollow, and the core sliding up and down inside is attached at the bottom to a link in contact with the frame L, which is centred at C. It will be noticed that there is only one pair of carbons, which are held in rack rods gearing into pinions on the same

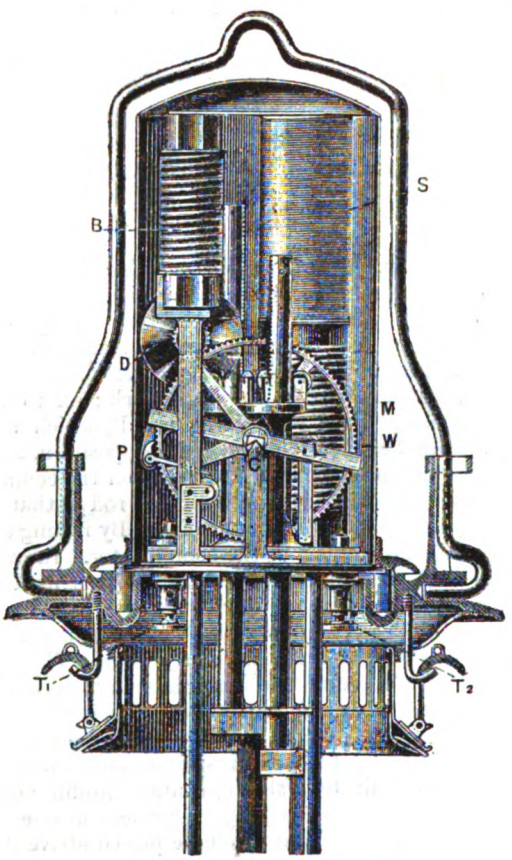

FIG. 5.—The Alioth Arc Lamp.

spindle as the large wheel W; being on opposite sides of spindle one rod rises as the other falls. When the current is started, the core that is in the centre of the two coils S and M is drawn downwards, lowering one side of the frame L, and raising the other with the catch or pawl, P, attached to it, thereby turning the wheel W, and separating the carbons. As the arc increases in resistance the shunt coil S receives more current, and the core is drawn up, thereby lowering the catch P, and allowing the carbons to approach. The upper carbon is more than double the diameter of the lower, and the lamp burns for 14 hours without renewal of carbons. The action of these lamps seems to be very regular and steady; 32 of them are arranged round one of the galleries, and joined up with four others at the stand, forming a series of 36 lamps, which are all run off one of the machines exhibited. A convenient lamp-pole is also shown, which is jointed about 4ft. from the ground in such way that the upper part can be lowered, thereby avoiding the use of cords, pulleys, &c., for lowering the lamp.

Among the instruments shown by MM. Alioth et Cie. is a coulomb meter of simple construction, though of somewhat cumbersome external appearance. It consists of a clockwork arrangement, made to run for 40 days, which drives a vertical spindle carrying a cylinder. This cylinder is partially covered by a brass hood shaped like a cone with its apex downwards, which, as it comes round, causes a wheel attached to the core of a solenoid to rotate. When the current passes through the solenoid it raises the core together with the wheel, and the more the wheel is raised the longer is it in contact with the cover of the cylinder during each revolution of the latter. The revolutions of the wheel are recorded by an arrangement of dials, and are obviously proportional to the ampere hours.

The ammeters and voltmeters show the same uniform principles of construction as those employed in the machines. The ammeters are constructed so that for a given deflection the ampere-turns are the same for all instruments. Thus, for an instrument reading up to 10 amperes there would be 100 turns, and up to 1,000 amperes one turn only on the bobbin. The core, suspended on a light arm and with pointer attached, is of flat, thin iron, somewhat resembling in shape that of the pocket ammeter now made by Messrs. Mayfield and Co. The movement is controlled by a fine spring of steel wire carefully hardened.

M. LEBLANC ON ALTERNATING MOTORS.

(*Continued from page 373.*)

(3.) M. Leblanc next deals with the condenser method, which, as has been already pointed out in these pages (*Electrician*, November 25th, 1887, p. 45), was first indicated by Mr. F. Higgins as long ago as 1878.

Consider a circuit with resistance R, and a coefficient of self-induction L supposed constant. Under an alternating E.M.F. of the form $E = E_0 \sin 2\pi \frac{t}{T}$ the apparent increase of resistance will be suppressed, or, as we should prefer to say, the inertia part of the total impedance will vanish, if we intercalate (in series) a condenser of capacity

$$K = \frac{1}{4\pi^2} \frac{T^2}{L}.$$

We shall omit the complete proof of this proposition, as it has already been given by more than one English writer. It should, however, be noticed that, strictly speaking, it holds good *only* under the assumption that L is constant, although if this be not the case the increase of apparent resistance is still diminished *pro rata*. The potential energy of such a system consists at each instant of the sum of the energy stored up by the self-induction of the circuit and of the charge of the condenser. The first is equal to $\frac{1}{2} L I^2$, and the second to $\frac{1}{2} K P^2$, where P is the difference of potential at the terminals of the condenser. This sum may be written

$$L \frac{E_0^2}{R^2} \sin^2 2\pi \frac{t}{T} + \frac{1}{4\pi^2 K} \frac{E_0^2}{R^2} T^2 \cos^2 2\pi \frac{t}{T};$$

and since by hypothesis

$$4\pi^2 K = \frac{T^2}{L},$$

the above expression reduces to

$$L \frac{E_0^2}{R^2},$$

which is constant (so far as L is constant). Hence the potential energy is constant, and the inertia part of the impedance vanishes.

The practical question is, of course, Can a condenser be made to fulfil the conditions of a practical engineering appliance, and, if so, what will be its size? Suppose we are limited to a difference of potential of 1,000 volts, and we take an air condenser with plates separated by half a millimetre, in which case there should be little danger of sparking through—then a capacity of 19·81 microfarads, say, 20 microfarads in round numbers, would be able to store 1 kilogrammetre (7·23 foot lbs.) of energy. [If, therefore,

Digitized by Google

such a condenser was fed with an alternating current with a period of $\frac{1}{100}$ sec., work might be done at the rate of 1,446 foot lbs. per second, or 2·63 horse-power.] Applying the usual formula, we find that a total surface of 1,131 square metres would be required, or as we could make use of both sides of the metal, we may say 530 square metres. The volume occupied would be a quarter cubic metre (nine cubic feet). But M. Leblanc thinks that we need not in reality confine ourselves to the comparatively low tension of 1,000 volts, nor do we need so considerable a thickness in the di-electric. Mr. Ferranti has found that a thickness of $\frac{1}{10}$ millimetre of gutta-percha will insulate a current of 100 alternations under a difference of potential of 15,000 volts. If we multiply the potential by 15, we can divide the area of the condenser by 225, and if we reduce the thickness of the dielectric we may again diminish the area *pro rata*. It must, moreover, be recollected that the area required varies inversely as the *square* of the periodic time of the current.

The condenser method demands, therefore, high potential and rapid alternations, and it would seem impossible at present to prognosticate with any degree of certainty whether in the progress of electrical engineering we shall or shall not move in the direction here indicated. At present, we should like to see Mr. Ferranti's experiments receive some further confirmation before accepting them as an article of faith. M. Leblanc, however, seems to feel no doubt as to the future of the condenser.

Meanwhile, he makes a suggestion which may, perhaps, be of immediate value in a particular case. This is for the suppression of the double set of leads of the Tesla motor. A good many suggestions have been made for this purpose, but although the use of a condenser seems tolerably obvious, we do not remember to have met with it before. It is only necessary

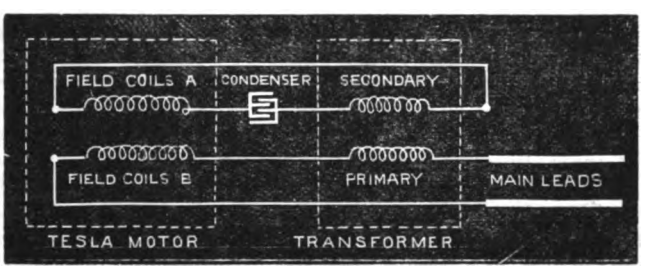

FIG. 6.

to take a transformer and equilibrate the self-induction of its secondary circuit (including in this, of course, the *external* circuit) by interposing a suitable condenser. The current in this circuit will then be displaced in phase by precisely one-quarter wave-length over that of the primary. The primary coil is placed in circuit with one set of the Tesla field coils, and the secondary with the other set, as indicated in the diagram (Fig. 6). We can, if we like, go a step further, and balance the self-induction of the primary also, so as to suppress the apparent increase of resistance of the system with respect to the generator.

M. Leblanc next embarks upon an *inquiry as to the best means to redress* an alternating current at the place of utilisation.* The author commences the inquiry with the following "*Remark*:—If the E.M.F. which acts upon a circuit is directed always in the same sense, the mean value of the current in the circuit will be independent of its coefficient of self-induction and will be equal to the mean value of the E.M.F. divided by the ohmic resistance of the circuit."

Need we say that this is a complete mistake? And although the assertion is subsequently backed up with an imposing display of mathematics, the error is not far to seek. M. Leblanc has chosen at a certain point to consider t very great, an hypothesis which does not alter the mean value of his integrals, but which limits the physical interpretation to the particular case when the periodic time is very great, which, we take it, is also the common-sense explanation. The author, however, arrives at the conclusion that "it results that a redressed current is as well suited as a continuous current to supply a motor. The inconveniences that present themselves in the employment of the currents relate not to their mode of utilisation, but to their mode of production." Having started on a false track, M. Leblanc pursues it at great length; he has a good deal more to say about the Mordey commutating motor (*The Electrician*, August 9, 1889, p. 346), of which, in principle, he highly approves, while he condemns the mode of commutation on the ground that the successive current-waves are separated by spaces of zero E.M.F., which is true enough. However, believing as we must that M. Leblanc has been led wholly astray on this point, we cannot devote further space to its consideration. We may just remark in passing that one solution to which a column of the original is devoted, requires as many wires between generator and motor as there are bars upon their commutators (!)

In concluding this section, we find one very novel suggestion which may conceivably be of some future use. The problem may be stated thus: Having an alternating-current of given period, to obtain a current of any other required period.

Take a Gramme ring, and divide the coils into three circuits, a, b, c, in such a way that every alternate coil all round the ring is in circuit c, whilst the remaining coils in each alternate *quadrant* belong to circuits a and b respectively. In fact, so far as a and b are concerned, the circuits are placed exactly as in the Tesla motor, whilst a coil of circuit, c, intervenes between every pair of coils all round. Through circuits a and b two independent alternating currents are sent which differ in phase by 90deg. again as in the Tesla motor. The coils of circuit c are connected to the bars of a Gramme commutator, and upon this, according to M. Leblanc's solution, a pair of brushes is caused to rotate. Now, whilst the brushes are at rest the coils c are the seat of an induced E.M.F. equal in period and midway in phase to that of the currents in a and b; but now, if the brushes rotate upon the commutator, it is easy to see that the period may be either diminished or increased, according to the relative velocity of the brushes as compared with that of the virtual rotation of the poles in the ring caused by the currents a and b.* M. Leblanc does not himself hint that the apparatus might be used for *increasing* as well as for decreasing the rapidity of alternation; but if the device can be put into practical shape it appears to us that the one arrangement is as likely to be of use as the other, always provided, however, the speed of commutation can be kept within limits. For experimental purposes a means of "speeding up" alternations would be very valuable.

* This is a useful word which we might as well adopt, as we have no exact equivalent in English.

[* See, however, a Note in our Editorial columns, added since this article was in print.—ED. *E.*]

REVIEWS.

Modern Views of Electricity. By OLIVER J. LODGE, D.Sc., LL.D. F.R.S. (London: Macmillan and Co. 1889.)

In this work, which is mainly a reprint of a series of articles contributed to *Nature*, Prof. Lodge has laid a lasting obligation of gratitude upon electricians. Gathering up from the researches of the most able and modern of investigators down to within two months of the date of publication, and adding to them the result of his own admirable and ingenious inquiries, he has now strung together and expounded in language as graphic as it is simple, those modern views of electricity which will assuredly in the main survive the present orthodox notions received by tradition from the electricians of an older generation. In all the older, and in much of the current literature of the science of electricity, attention is concentrated upon the so-called conductors of electricity; and all the facts are discussed, and the definitions framed, nay, even the language of the science is based upon the assumption that it is upon the conductor that the static charge accumulates, and that it is through the conductor that the so-called current flows. In the modern view of the subject, attention is concentrated not upon the conductor, but upon the medium in which it is immersed. Franklin first showed that it was the medium between the two metal plates, not the conducting metals, which really became charged. But to Faraday we owe the really great

Digitized by Google

advance of considering the medium surrounding the conductor as the seat of those actions, both electric and magnetic, which accompany any and every movement of electricity. The dielectric capacity and magnetic permeability of media have in the last forty years been measured by many observers. Sir William Thomson introduced magnetic permeability into the theory of magnetism. Maxwell cast into mathematical mould the ideas involved in the introduction into electrical theory of the inductive capacity of the medium. Poynting and Heaviside have more recently wrought out in mathematical shape the problem how the medium can transfer electrical energy from one part of an electric system to another. Maxwell, by a daring stroke of scientific speculation, founded the electromagnetic theory of light, a theory already, by the labours of Hertz and by those of Prof. Lodge himself, amply verified and proven. But until now no one has dared to depart so far from the beaten track of orthodoxy, as to restate for popular instruction (using the word popular in its best sense), the modern science upon these new lines. Some of us have timidly suggested a point here and there; we have now to greet the man who has dared, and to welcome to his triumphs, the exponent of the modern views. Prof. Lodge, in a work of a thoroughly readable sort—though the reading is by no means all easy—and with much originality, and not a few pungent hits at friends and foes, has set forth the doctrines of electricity as a property of the medium—the ether—carrying the ideas of Faraday and Maxwell to conclusions, which, if not always final or probable, are yet logical, and of immense importance as suggestions for further lines of research.

Prof. Lodge divides his work into four parts, viz.: (1) Electricity at rest, or static electricity; (2) Electrici y in locomotion, or current electricity; (3) Electricity in rotation, or magnetism; (4) Electricity in vibration, or radiation. To the e, which constitute the body of the work, are added reprints of three lectures—(1) The relation between Electricity and Light; (2) The Ether and its functions; (3) The Discharge of a Leyden Jar. There is a brief appendix, to which some mathematical formulæ are relegated.

The most original feature of the book now be'ore us is undoubtedly the attempt to illustrate by quasi-mechanical models the ether-theory of electricity. In one set of these models a cord passing over pulleys is employed to illustrate a circuit, resistance to conduction being typified by frictional obstruction to motion, whilst elastic connections, which allow not of continuous motion, but of a yielding displacement, typify the quasi-elastic constraint offered by dielectric bodies. With this model, or rather with a set of such, are illustrated the author's views upon electrolytic conduction and on thermo-electricity, and they are most successfully employed to render clear and plain that by no means ordinarily clear or plain matter, the residual charges of a Leyden jar, and the apparent "soaking-in" of the charge arising from the heterogeneity of the dielectric. Another model, p. 173, elegantly illustrates the principle that there is a tension along, and a pressure in every direction across a magnetic line of force. This model is a centrifugal apparatus, and is introduced in connection with the theory that magnetism is electricity in rotation, each magnetic line of force being considered a vortex-core. The model would, however, equally well illustrate the tension along and pressure across an electrostatic field, concerning which there is in the modern view no such vortical action going on. Most important, however, of the quasi-mechanical models is the set for illustrating the constitution of the ether. According to Prof. Lodge's views on this latter question—views which he himself appears to regard only as tentative—the ether consists of two elements or kinds, which for want of a better knowledge may be called respectively "positive electricity" and "negative electricity," each of which elements is, as the joint ether itself is also, an incompressible fluid, otherwise called a *liquid* (pp. 12 and 65) It is, however, perfectly mobile with respect to all mechan'cal displacements, allowing solid matter to move through it freely. But with respect to all electrical forces it is quite otherwise, being exceedingly rigid toward all causes or agencies which would tend to shear away its positive elements from the negative ones. A strain in this medium produced by an electromotive force or shear, is only another name for an electric charge. A slip in this medium where its elements actually slide past one another constitutes what we ordinarily call an electric current. A medium so constructed, if it could exist, would certainly "behave in a very electrical manner" (p. 61). It is for this reason that a very large portion of the "modern views" is devoted to models carrying out this idea. In 1861, in the April number of the *Philosophical Magazine*, Maxwell published some curious speculations about a mechanical model of a magnetic medium, the parts of which were geared together by toothed wheels. To turn the mechanical difficulty that with toothed wheels directly geared, a rotation given to one part of the medium would set up in the surrounding medium a rotation of an opposite sign—whereas analogy required a similar rotation—Maxwell had introduced the well-known mechanical device of intermediate "idle-wheels," freely confessing, however, that they corresponded to no known entity. Prof. Lodge starts from Maxwell's model, but gives to the idle-wheels a new and startling significance. The medium consists of alternate sets of positive and negative wheels geared into each other so that all the positive wheels turn one way at once, and all the negative wheels turn the reverse way; and he assumes that the *reverse* rotation of the *negative* wheels shall be considered rotationally as a positive spin, so that though the individual parts may be spinning in opposite senses, the medium considered as a whole may be considered to have electrically a spin in one sense only. Concerning this notion of the medium or ether as consisting of rows or lines of wheels or cells of positive and negative electricity alternately placed or geared, we shall have something more to say presently. Having devised the medium so connected in its parts, the author goes on to explain by its means how in an insulating medium the gearing is perfect, but the wheels elastic, and how in a conducting medium the wheels are not perfectly geared by teeth, but allow of a certain amount of slip, slip being accompanied by frictional dissipation of energy. "The process of slip which we have depicted goes on in all conductors conveying a current, whether steady or variable, and in fact *is* the current" (p. 192). This ingenious method of considering the action of the medium leads to several most interesting lines of thought, which, however, cannot be followed in a brief review; suffice it to say, that in Prof. Lodge's hands it gives a good account of the induction of currents in adjacent conductors, and of the phenomena of the skin-flow of variable currents in conductors which, as the researches of Prof. Hughes have pointed out, increases their resistance. But the consequences of the new view will somewhat perplex electricians of the old school. Ohm's law they now meet with under the guise of a law of electric friction: "it asserts a connection between matter and electricity," "it asserts that when electricity flows through matter the friction between them is accurately as the first power of the velocity for all speeds" (p. 119). Further, the function of the telegraph wire or conducting line is not to conduct or convey anything, not even an impulse. "The function of the wire . . . . . is to dissipate the energy crowding into it from the medium, which else would take up a static strain and cease to transmit any more" (p. 96). "This is the function of the wire; it guides the effects transmitted through the dielectric" (p. 201). "The wire dissipates energy, it transmits none; all that enters it is lost. The dielectric alone, with its cogged-gearing, transmits energy to the distant station" (p. 202).

(To be continued.)

The Working and Management of an English Railway. By George Findlay (General Manager of the London and North-Western Railway). (London: Whittaker and Co., 1889.)

This interesting volume owes its origin to a lecture delivered last year at the School of Military Engineering at Chatham, and now expanded to its present form. We have here a clear and detailed account of one of the most gigantic, as well as one of the most successful, organisations of human labour in this or any other country. Every one who has ever thought at all upon the subject has probably recognised that the smooth and regular working of a great railway system must depend upon the existence of a system of gradu-

Digitized by Google

ated responsibility elaborated with the greatest care and skill, and maintained inviolate in its minutest detail. We are here shown how and by what means such an organisation is carried out in practice, and we find also a most interesting account of the mechanical equipment in the departments of "permanent way" and "rolling-stock."

One chapter is devoted to the Telegraph service, which is to the actual railway line what the sensory nerves are to the muscular system. The London and North-Western Railway route now carries no less than 18,115 miles of wire, of which, however, 6,877 miles belong to the Post Office. No less than 100,323 battery cells are in use. The block signal apparatus was first introduced by Mr. E. Clark, in 1853, though it has since been simplified in working and improved in detail by Messrs. W. H. Preece, E. Spagnoletti, G. E. Fletcher, and others. It was not, however, until the year 1879 that it was found practicable to work the block telegraph through busy station yards. In that year Mr. Tyers introduced his so-called "Telltale" instrument, by which the signalman on making a forward signal receives a reminder of the number of trains in the section in the rear. In addition to this apparatus, considerable use is now made of the Telephone in the working of the more important station-yards. The regular conduct of the line has been still further facilitated by the introduction of electric signal repeaters and light indicators, by which the signalman is able to ascertain whether a signal which may be out of sight has actually obeyed the motion of the levers. This arrangement was first employed, we believe, on the Great Western Railway by Mr. Spagnoletti, but the particular form of apparatus in use on the London and North-Western Railway was designed by Mr. G. E. Fletcher.

Handbook to the London University Matriculation Examination (London: The Electrician Printing and Publishing Company.) Price 2s. 6d., post free 2s. 9d.

This handbook, which is a substantial volume of nearly 200 pages, contains the papers set in June, 1888, and January, 1889, at the London University Matriculation Examinations, each paper being immediately followed by full solutions to the questions asked. There can be no better employment for the last few weeks before an examination than a careful study of the papers which have been previously set. A large proportion of failures is, we are confident, due rather to unfamiliarity with the examiner's style of question than to the ignorance of the students. Handbooks of this description are invaluable as a supplement to the text-books usually studied by students preparing for examination.

Electric Bell Fitting. (Woodhouse and Rawson United (Limited) London.)

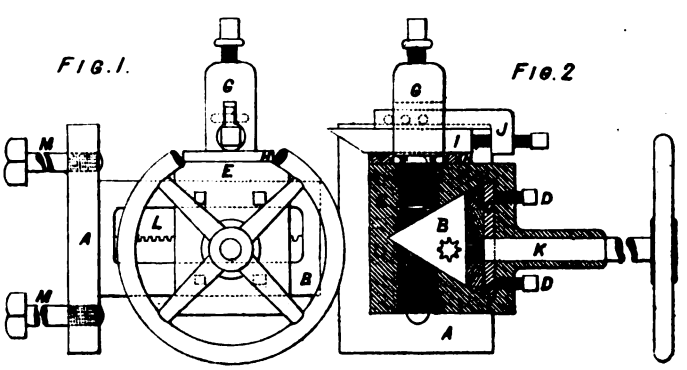
We have received from the Woodhouse and Rawson Company an unpretentious little pamphlet on the subject of Electric Bell-Fitting. The book, which is illustrated, is intended as a guide to workmen, and will admirably serve this useful purpose. Customers of the firm are supplied with the book free of charge, and we understand that a copy can be obtained on application.

A SLIDE-REST FOR COMMUTATORS.*

BY LEWIS F. LYNE.

One of the most difficult operations to be performed in connection with an electric light station is the turning up of commutators on the dynamo machines. They are sometimes put between the centre of a lathe and turned up in the ordinary manner, but this procedure, although successful so far as the turning process is concerned, has its particular objections. In the first place, the shaft is probably sprung somewhat in securing the armature, so that it will not run true. Frequently in boring the hole through the hub, hard spots will be encountered, and when the set screws are tightened to secure the armature, the shaft has to accommodate itself in a measure to the shape of the hole. Again, the wear upon the journals has a tendency to throw the shaft out, as the metal may be closer grained upon one side of the journal than upon the other, or it may have hard spots in it. The shaft may also have been turned in a lathe where the live centre did not run true; so you see there are many little things that are likely to occur in every-day practice which would prevent us from truing up commutators on lathe centres in the manner just described, and making a good job. In fact, I have seen these commutators trued up in this way run out a good thirty-second of an inch. Such a commutator when put to work, running 1,200 to 1,400 revolutions per minute, will spark at the brushes terribly, for the reason that the brushes cannot be kept in good contact with the surface of the commutator. The dynamo man will generally screw down upon the brushes, so as to get a better contact, and as a natural result tears the surface of the commutator all to pieces by abrasion of the parts in contact. I would much rather, without removing the shaft and armature from the machine, hold a piece of chalk close to the surface of the commutator and rotate it so that the chalk will touch the high spots and leave its mark. Then with a file remove the protuberances, and gradually by numerous trials work the surface down to its original condition.

This and other similar experiences led me to design and make the slide-rest shown in the accompanying engraving. The dynamos I had in charge were of the Fuller-Wood and Ball types, where to turn the commutator one has about 7in. in length, and has to work in between the end of the dynamo frame and the end of the armature. Therefore I could not use a screw to feed the tool on my slide-rest, so I adopted the design here shown in Figs. 1 and 2. I had a triangular-shaped slide made with a flange, A, at one end, 3in. wide, 6in. long, and ⅜in. thick, for the purpose of bolting or clamping this slide-rest to the end piece of the dynamos. The slide B is 6in. long and 3in. across the sides of the triangle.



This peculiar form makes a very stiff slide, and the lost motion is readily taken up by one gib, C, adjusted by four set screws, D. The rest E is made of brass, for convenience in working, as well as economy. A hole, F, was drilled and tapped with the 1in., eight threads to the inch, straight through, so that by changing the tool-post G from one side to the other the slide-rest may be in a few seconds converted either into a right or left-hand, as desired. By placing the washer H under the tool I it may set in any desired position. A gib, J, provided with holes and a pin as shown, placed on top of the tool, furnishes a ready means of adjusting and feeding the tool endwise by simply turning the set screw which presses against the butt end of the tool. The rest E is fed longitudinally by means of a small pinion cut in the end of the shaft K, gearing into the rack L. For clearness a portion of the slide B is shown, broken away to exhibit the rack, and an end view of the pinion is represented to show the eight teeth. The rack is held by two screws in a recess cut for its reception, and the shaft K is loose so that it may readily be withdrawn for convenience when putting the rest away after use. By turning the 6in. wheel the tool may be firmly and easily fed as desired. The two ⅜in. bolts M M, with iron clamps and suitable blocking, will enable the workman to attach this slide-rest to almost any style of dynamo. I use bolts of different lengths, so that we can readily attach it to any one of the fifteen dynamos placed in my charge. I never use power from a belt to drive the dynamo while I am turning off the commutator, but use instead a lathe dog with a long tail which forms a crank. This dog slips over the end of the shaft and a labourer furnishes the power to rotate the armature at the speed desired. For machines where this dog cannot be used, I have a crank that can readily be clamped to the rim of any pulley, and so accomplish the desired end. In reference to the rapid operation of this tool, I may say that I have often turned up commutators that were badly worn, in from ten to twelve minutes.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

RAIDING THE LOCAL AUTHORITIES.

The list of Provisional Orders, of which notices have been served upon Local Authorities, published in our last week's issue, appears to have created some surprise, both in respect to the number of applications and the manner in which they are distributed. The raid on the provinces has been carried on with much vigour down to the very last moment at which notices could be served so as to be in time for the Parliamentary Session of 1890. Our readers have now had time to study the list, and, aided by the epitome furnished in our leading columns, they are in possession of material for forming an opinion on the general situation. In attempting to estimate its true significance, however, it is very necessary to remember that the mere serving of a notice upon the Local Authority is a step which anybody may take at the expenditure of a postage stamp, and which does not necessarily entail any further responsibility. As a matter of fact, the Local Authority may never hear further on the subject. Upon the whole, we are inclined to think it a pity that the Act, or the Board of Trade under the powers conferred by it, does not insist on a deposit of substantial caution-money at this stage as a guarantee

Digitized by Google

of good faith; for, as we have already hinted, it is impossible, on closely examining the list, to avoid the suspicion that many of them are mere fishing or speculative notices which will never be proceeded with. If the credit of the electric light at this critical juncture were not at stake we should be content to see these will-o'-the-wisps compelled to try their best and worst at their own expense. But under present circumstances we trust that the Board of Trade will do for the provinces what it has done for the Metropolis, and by subjecting the applicants to a close investigation of their financial and technical resources, effectually extinguish the pretenders. And this course, we contend, ought to be followed whether there are competing applicants or not; for no doubt the idea which has prompted the wholesale scattering of notices is that legitimate applicants would be to some extent kept off by the expense and inconvenience attending a formal Board of Trade inquiry where competing claims have to be contested at every point. If it were understood that a local inquiry would take place in any case, it would do much to induce many of the companies to disappear from the scene altogether.

One of the most striking features of this extraordinary list of notices is the overwhelming preponderance of a single company and its offshoots, who down to the present date have taken preliminary possession of by far the greatest and most important areas outside the metropolis. It would, of course, be a little rash to suppose that there is any real intention to proceed in many of these cases to which we allude, yet the appropriation of about one-half of the whole number of notices by one company looks like rushing the business with the object of frightening off competitors. We do not pretend that these proceedings afford any legitimate ground for complaint against the companies in question—from a purely commercial standpoint their tactics are probably very sound, they get an excellent advertisement in all the towns in question, and they will be able by-and-bye to select for further operations those localities which may appear most worthy of attention. But we cannot help deprecating the manœuvre in what we believe to be the best interests of the industry. We want, if possible, to have done with the era of abortive efforts and Stock Exchange manipulation, and to settle down to good, solid work. But apparently this is still as much as ever a Utopian dream.

But perhaps the hardest case of all is that of the local authorities themselves, who, pelted with these missiles, have to make up their minds to either tamely surrender, or promptly find a stick to lay on their own backs. Before the end of November they must give notice of their own intention to supply the electric light, which they do not like to do, or allow somebody else to step in and do it, which they like still less. We frankly admit that in many instances neither of these alternatives can be kindly entertained by the townspeople concerned. We have always held the opinion that the electric light business would have fared better to be left alone to grow naturally without artificial restrictions on the one hand or compulsory powers on the other—although under the circumstances this was perhaps impossible. Accepting, however, the law as it stands, the difficulty may perhaps be got over by taking counsel with the best known electric lighting supply or manufacturing companies, and putting forth all their strength against the intrusion of speculators on whom the towns can place no reliance. Those towns which finally decide to supply their own electricity will have no difficulty in finding the necessary plant and professional help by paying for them. Where private venture is preferred, the local authorities ought to give their strong support to the particular company or firm they have confidence in. One or other of these courses they ought to adopt, and that speedily. Our object in offering these remarks is to help them to make their choice wisely.

In making this choice the Local Authorities have clearly to understand they are not free to exclude outside Undertakers by a merely passive resistance. Specific and reasonable cause of objection must be shown to any proposed Provisional Order—general objections to the introduction of electric lighting weighing but little with the Board where there is reasonable ground for believing that the inhabitants are anxious to be placed in a position to obtain its advantages. The most effective obstacle they could interpose would be, of course, an application for a Provisional Order by the Local Authorities themselves. Here the temptation will arise to take that course without any serious intention of following it up. But this again will not serve their turn, for if they obtain the Order they will be bound, like ordinary Undertakers, to supply electricity on demand within a period determined by the Board of Trade in granting the Order. In the recent discussion at Manchester, it seemed to be thought that "there was no hurry to decide anything as they had three years to look about them." They will soon find out that there is something more to be done in that time than looking about; and meanwhile they have to come to a decision in little more than three months.

THE CHELSEA ELECTRICITY SUPPLY COMPANY'S INSTALLATION.*

The following description of a typical installation of the Electrical Power Storage Company's system of distribution, such as the one now working at Chelsea, which has been carried out by the Anglo-American Brush Electric Light Corporation (Limited), the Callender's Bitumen Telegraph and Waterproof Company (Limited), and the Electrical Power Storage Company (Limited), may probably give the best idea of the working of the system. The dynamo plant consists of a number of dynamo machines, each of 500 volts, and capable of giving a current of 75 amperes, placed in series with each other until the limit of electromotive force in the charging circuit is reached. These dynamo machines are driven, in the case of the Chelsea Company's installation, from separate Willan's, or other high-speed engines, coupled direct. The magnetic fields of the dynamo machines are excited by means of a separate compound-wound dynamo machine and engine, which is solely devoted to this purpose and the lighting of the engine-room. At the generating station there is also a storage station, and the charging current is applied to this first, or No. 1, storage station, in series with No. 2 and No. 3 storage stations, in suitable localities in the district.

The storage battery in each of the Chelsea Electricity Supply Company's sub-stations consists at present of 8 sets of 54 L-31 E.P.S. cells, in glass boxes. These are of the latest and most approved form, generally known as "1888" type, in which the plates are supported clear of the bottom of the cell, or containing vessel, by means of a footlike prolongation of the bottom corners of the spongy lead plates, and the peroxide plates are carried on an insulated saddle bar forming a metal connection along the edges of the spongy lead plates.

The cells are carried in varnished wood trays on sawdust or felt, the trays being supported on oil insulators which are carried by wood beams resting in sockets of strong cast-iron standards which carry from 3 to 5 tiers of cells according to the available height of accumulator room. Along the top of these iron standards a pair of rails is laid and an overhead gear of simple and convenient construction enables the attendant to put a cell into place in the circuit, or to remove one if desired, in a few minutes.

The floor space required per 1,000 lamps of 30 watts is 225 square feet, equal to 1·125 square feet per cell and 0·225 square feet per 30 watt lamp when the accumulator room in the storage station is 9 feet in height.

The batteries are charged in series of four sets of 54 cells in each station. The principle of the system is that it is impossible for the supply circuit to be interrupted, that is to say, for both halves of the whole battery, or more than four sets of 54 cells in each sub-station, to be charging at any one time, the other half or four sets in each station being applied in parallel to the supply circuit. Considerable misconception has arisen respecting this point, and it

* Extracted from a Pamphlet issued by the Electrical Power Storage Company.

Digitized by Google

must be understood that the whole battery in each sub-station, which is capable of supplying 2,000 lamps of 30 watts, is charged in *two distinct halves*, and there are *not two whole* batteries. The charging process will usually commence at about 4 a.m., and the operation will be as follows :—

After getting up steam in the usual manner, the engineer in charge completes an electric circuit by a switch at the generating station, which has the effect of placing the first half battery in each accumulator or sub-station on to the circuit of charge, and all the accumulator stations in series. A voltmeter at the generating station applied to the charging leads then indicates the electromotive force of the batteries thus placed on the charging line, and it is only necessary to run the charging dynamos to give the same electromotive force on open circuit, when they may be switched into circuit with the batteries, the speed of the dynamo machines, or the strength of the magnetic fields being then gradually increased until the proper charging current is reached.

Assuming that the first half-battery in each sub-station may take, say, six hours to charge sufficiently to make up for the consumption of the previous day, it will then be charged by 10 a.m. The charge being complete, evolution of gas from the spongy lead plates takes place, and the gas which is given off from the end plate of one cell (technically known as the "Master" cell) is collected in a chamber fixed above the plate, and passed on by a tube connecting the said chamber to a gasometer, which is fitted with a relief valve controlled by the current in the charging circuit. The gas accordingly fills the gasometer and causes its movable portion to rise, and thus actuate the switching gear attached to the transposing switches, causing No. 1 half of the battery to be removed from the charging circuit to the circuit of supply, while the continuity of the charging circuit is maintained by switching a resistance into parallel with the half-battery as it is being switched from the charging circuit to the circuit of supply, and keeping the resistance in this position for about half a minute, while the second half-battery is being removed from the circuit of supply to that of charge. This latter operation takes place owing to the relief valve of the gasometer being opened by the cessation of the charging current in the charging circuit of the batteries, thus allowing the collected gas to escape, and bringing the movable portion of the gasometer with its attached switching arrangements into the original position whereby it places the batteries into the charging circuit. The charging process is thus continued, but only as regards the second half of the battery in the storage stations, and when at, say, 4 p.m., the second half-battery has been filled, gas is again evolved from the spongy lead plates, and by a repetition of the previous action of the gasometer, the battery is removed from the charging circuit and placed into parallel on the discharge or supply circuit with the first half of the battery which had been charged in the early portion of the day.

Should it be found necessary during the darker months of the year to augment the capacity of the sub or accumulator stations during the two or three hours of maximum lighting in the evening, the charging current from the dynamos may then be connected to a continuous-current transformer in each subsidiary station. The motor coils of this transformer, on being supplied with a high tension current of *constant quantity*, similar in fact to the usual charging current and generated by the usual charging dynamo machines, causes the generator coils to yield a low tension current equal in electromotive force to that existing on the supply circuit at the battery terminals, and also of *constant quantity, whatever be the conditions of resistance of the supply circuit.* By working the charging dynamo machines at their normal capacity, and using the current as above described for actuating continuous transformers, the capacity of each storage station to give supply of electricity to consumers is increased by 50 per cent., and in consequence a large increase of earning power, involving a very small additional capital expenditure, is added to the capacity of the plant as a whole.

It will be understood, therefore, that generating plant and dynamos indicating *one-half of the maximum capacity of the system* is sufficiently ample (this amount including a due proportion of spares, which proportion is, however, less than is possible on any other arrangement, in consequence of the long time at the disposal of the engineers in charge for making repairs), the storage capacity being always sufficient for two-thirds of the maximum demand.

In considering the respective advantages of various systems, the question of space and dimensions of generating station should receive due prominence. It is comparatively easy to obtain premises, &c., to accommodate generating plant for, say, 15,000 lights, and this would supply on the E.P.S. system 30,000 lights, whereas on systems without storage a proper provision of spares or reserves would entail space and machinery for 40,000 to 45,000 lights, and on parallel systems using only a small proportion of storage as reserve, machinery capable of working the whole 30,000 lights would be needed.

The regulation of pressure or electromotive force in the distributing mains is attained by means of the introduction into the discharge circuit of counter electromotive force cells controlled as follows :—A solenoid core is suspended against the action of gravity by the magnetic field caused by placing the coil in parallel with the distributing mains. Any rise or fall in the electromotive force at the mains is communicated to the core, and contacts are made by the movements of this core which actuate simple switches for inserting or removing from the supply circuit counter electromotive force cells giving a difference of potential of from 2 to 2½ volts each. A mean regulation with a variation of not more than 1½ volts on either side of datum is thereby maintained, so that in a 100-volt circuit the lowest possible potential on the mains will be 98½ volts, and the highest possible will be 101½, the average being very nearly the normal figure of 100 volts.

The apparatus for effecting the various transpositions of the secondary batteries and for maintaining the pressure constant is entirely automatic, the movable portions being worked by the energy which would otherwise be wasted in the counter electromotive force cells, which are used for regulating the pressure on the supply mains ; the result is that all the actuating portions of the apparatus require current at an electromotive force of only 4 or 5 volts, and it is therefore cheap to manufacture and exceedingly reliable. The operations of breaking and making circuit are performed without sparking, and the loss of energy in the apparatus is so small as to be quite unimportant. Attention is directed to the fact that the possible loss of automaticity of the apparatus will not do any damage to the plant nor cause other inconvenience than the presence of an attendant while repair is being made.

PARIS INTERNATIONAL ELECTRICAL CONGRESS.

The following programme has been issued by the Congrès International des Électriciens :—

SATURDAY, August 24th.

10 a.m. Inaugural Séance at the Salle des Conférences du Trocadéro. Nomination of the Bureau. Formation of Sections. Division of labours.

8:30 p.m. Electric Undulation Experiments by M. EGOROFF at the Société d'Encouragement, 44, Rue de Rennes, Place Saint-Germain des Prés.

SUNDAY, August 25th.

8 a.m. Ascent to the third story of the Eiffel Tower. Visit to the instruments of observation. [N.B.—Members of the Congress who enrol themselves at the inaugural Séance will be taken up half-price.]

MONDAY, August 26th.

Meetings of Sections, and visits to the Exhibition, organised by each section.

TUESDAY, August 27th.

Meetings of Sections in the morning.

2 p.m. Visit to the Laboratoire Central d'Électricité, and to the works of the Société Générale des Téléphones and of MM. Sautter et Lemonnier.

WEDNESDAY, August 28th.

Meetings of Sections and visits to the Exhibition.

THURSDAY, August 29th.

2 p.m. Visits to the Palais Royal and Opera Central Stations.

FRIDAY, August 30th.

Meetings of Sections and visits to the Exhibition.

SATURDAY, August 31st.

General Séance and close of the Congress.

7:30 p.m. Banquet at the Hôtel Continental, given by the French members of the Congress to the Foreign members.

(i.) During the Congress, visits—the dates of which have not yet been fixed—will be made to the central lighting stations and private installations at the Exhibition.

(ii.) There will be Special Séances for the members of the Congress to hear the Edison phonograph and telephonic auditions in connection with the Opera, and to witness the electro-dynamic and electric welding experiments of Professor ELIHU THOMSON.

(iii.) Any information may be obtained at the Société Internationale des Électriciens, 44, Rue de Rennes.

From the Reports presented to the Congress we have selected the following :—

The Measurement of Energy.

REPORT BY M. A. POTIER.

At the time when dynamo-electric machines first came into commercial use, the question of efficiency was of secondary and theoretical importance. An efficiency equal to that of a sufficiently powerful battery was all that was expected of them, and their general superiority was so obvious that no one dreamt of taking the trouble to take exact measurements. In a large number of installations, even in these days, owing to the power absorbed by the dynamos being but a small fraction of the total power used, the excessive absorption of power by the electric lighting machines is masked, and the only thing required of the dynamo is regular working. Now that the applications of electricity have become more numerous, that we are attempting long distance distribution of energy, and that an active competition exists between different types of machines, the efficiency of a dynamo is an important commercial factor. It seems useful to exactly define what we mean by efficiency, and to agree as to the methods of determining it.

We define the efficiency of a dynamo, whether motor or generator, as the ratio of the useful energy to the energy expended ; electrical energy being measured at the terminals of the machine, whilst the work, in order to avoid the uncertainty of transmission arrangements, should be measured on the shaft of the machine itself. The efficiency of a motor can generally be determined with exactness, except at high speeds. Brake indications are very accurate if the requisite and well-known precautions are taken, while electrical measurements can be made with even greater accuracy. The efficiency of a generator is also easy to determine when an appropriate transmission dynamometer is available, but unfortunately these complicated and costly instruments cannot be improvised like brakes, and their indications may be falsified if the speed exceeds a certain amount, so that each apparatus is only useful between rather narrow limits. Dynamometers in which the difference of tension of the two halves of a belt is measured seem, moreover, by no means over-accurate. It has also been sought to determine the efficiencies of generators without having recourse to these dynamometers, especially in the case of large machines. We can also proceed by a method of substitution, and, after having obtained from an indicator diagram the work done on the piston at different speeds, and the electric horse-power of the dynamo, substitute a brake-pulley for the dynamo. In this way, if we admit that the efficiency of the steam-engine and of the transmission gear has remained the same under practically the same conditions of speed and power, we have the necessary data for the calculation of the efficiency of the dynamo.

In the case of two machines, the efficiency can be determined by the method employed by the Drs. Hopkinson. The two dynamos are mounted on the same spindle, and united electrically in opposition, so that one works as a generator and the other as a motor. A dynamometer, which may be a small one, measures the power transmitted to the system, power which is entirely absorbed by the passive resistances, Foucault currents, and in heating the coils of the machines. This method has been modified by Mr. Ravenshaw, who suppresses the dynamometer and introduces a third dynamo, driven by the same engine, into the circuit of the two first, the power which this last machine furnishes being determined electrically. If we call this third dynamo C, and the two other dynamos A and B, the ratio of the differences of potential at the terminals of A and B gives the efficiency of the system A B. Let R_3 be this efficiency. We can determine by the simple comparison of two electrical measurements the efficiency R_2 of the system A C, and finally the efficiency R_1 of the system B C. If we call r_1, r_2, r_3 the individual efficiencies of the machines, and if we suppose that they are the same in all three experiments, then $r_1^2 = \frac{R_2 R_3}{R_1}$. It seems doubtful if this method can lead to accurate results, for the efficiency of a machine varies with the intensity of the current which traverses it and with the speed, and it does not seem possible to run the machines in the three experiments at their normal load and velocity.

M. Fontaine has used a simpler method based also on the employment of three machines. Machine A is mounted on the same shaft as machine B, which runs as a motor, the current being furnished by a third machine, C. The machine A is outside the circuit B C, and is closed on a circuit, whose resistance is regulated so that the current in it is the same as that in B C. The ratio of the differences of potential at the terminals of A and B gives the efficiency of the system A B. When the two machines are identical M. Fontaine admits that the efficiency of each is the square root of the total efficiency, which amounts to saying, as is done in the case of the methods derived from that of Hopkinson, that the efficiency is the same whether the machine is a generator or a motor. Upon this hypothesis it would be easy, by making three experiments, to determine the individual efficiency of each machine. These two methods (those of Ravenshaw and Fontaine) seem very suitable for the rapid comparison of the efficiencies of machines of the same type ; but the moment we admit the equality of the efficiencies, the use of transmission dynamometers becomes unnecessary, and the brake test should suffice when it is a question of determining the efficiency of a single machine. But a reservation is necessary ; it is not permissible to say that the efficiency is the same for two identical machines working under the aforesaid conditions. The efficiency of the two-machine system may be *nil*, for instance, without that of the motor being *nil*. It seems more rational to say that, for equal magnetic fields and armature currents, the losses due to Foucault currents and friction of all sorts are the same for equal speeds. In M. Fontaine's method, for instance, if $\frac{100-x}{200}$ is the efficiency of the system B A, composed of two identical machines, the efficiency of B should be $\frac{200-x}{100}$, and that of the generator A $\frac{200-2x}{200-x}$. Following out the same idea, if $\frac{100-x}{100}$ is the efficiency of a motor, its efficiency as a generator, under the same conditions, would be $\frac{100-2x}{100-x}$.

If careful experiments confirmed these views, a series of brake tests—tests which engineers consider to be capable of being made very accurate—would be sufficient to determine the efficiency of a generator under the various conditions of working. It would be interesting to know between what limits we may consider the efficiencies as equal ; or, in other words, the losses of the same machine working as a motor or as a generator as equal.

In shops where several machines are available it would always be possible to determine the efficiency of a generator without employing a transmission dynamometer. My experience has shown me that up to 50 horse-power, at any rate, a motor is an excellent dynamometer. If we measure on the brake the power furnished by the machine, we shall always find within the limit of error the same efficiency when the machine works under the same conditions of speed and load, although the E.M.F. may slightly vary, the machine, of course, running in its normal condition as regards lubrication. We can therefore test a motor at a series of speeds, form a table corresponding to a series of current intensities, and this done with all possible care, the test of the generator would be made by merely coupling it to the motor shaft and comparing the number of watts furnished and absorbed by the two machines. It is evident that this method would be equally applicable to the measurement of the efficiency of an alternator. It has the decided advantage that the forces applied to the machine to be tested are reduced to a simple couple. By the suppression of belts we eliminate an error, which it is impossible to determine, arising from the variable tension of the belt, an error which the use of dynamometers does not efface.

If, on the occasion of the Exhibition, competent men were enabled to exchange views on this question of efficiency and succeeded in laying down a few uniform rules, it would be a great advantage to dynamo designers and those who use them.

Telephony.

REPORT BY M. DE LA TORRANNE.

Telephony, by rare good fortune, has in less than ten years extended over the whole world, and an instrument regarded at first as a scientific toy, has become the foundation of an industry which extends its domain from the village to the largest cities. But the very rapidity of its development has brought with it a certain element of danger. No sooner is one arrangement adopted than another more ingenious and more practical follows, and we have seen a company solicitous for its good name positively sweep away a system which it had only just brought into use, and proceed to reconstruct the whole from the commencement. Now, although we can never hope to get wholly beyond the necessity for improvement, yet such wholesale changes might often be avoided if there were more frequent opportunities for the interchange of experience amongst practical men. Questions concerning lines, apparatus, exchanges, and tariffs present themselves under a hundred different aspects, and their consideration will have great interest amongst those who are competent to discuss them in the light of experience.

For the lines, universal opinion seems to point to the use of copper and its alloys. But we have yet much to learn as to the conditions under which it is advantageous to use either of the bronzes, or hard or soft copper. The latter, by reason of its low tensile strength, seems reserved for cables, but the former varieties have probably scarcely yet arrived at their definitive form. Many types have been proposed ; what are their precise specifications, and what their advantages and disadvantages ? At what resistances, at what capacity do we stop short in practice ? How many wires is it convenient to put in a single cable ? What modifications is it desirable to make in constructing a cable, according to whether it is to be used for single or metallic circuits ? Upon this point of metallic circuits, how are the overhead lines best arranged ? Is it not possible to use a common return wire for such circuits ? In that case how should the wires be run upon the poles ? These are some of the questions which may be discussed.

Telephonic apparatus does not afford us a very wide field for remark. The multiplicity of models of microphones, telephones and signalling apparatus, due to the fertile imaginations of the inventor, renders it difficult to classify them. Often the differences are of no commercial importance. . . . . The great majority of the auxiliary apparatus used in telephony are merely adaptations or modifications, more or less happy, of well-known devices used long ago in telegraphy. . . . . .

As regards the central stations or exchanges there are many points which merit special attention. As to switchboards, what facilities ought they above all to present ? What is the smallest number of subscribers which renders the multiple system indispensable ? Everything should be sacrificed to secure the rapid and correct working of the system. . . .

But the most perfect appliances will be thrown away unless we have a thoroughly good system of regulation and supervision over the *employés*. It will then be interesting to compare the various regulations in vogue in different places. Another class of questions to be considered is such as this : Whether a subscriber who asks for a connection which cannot at once be made, should be left to call again or should have the connection made for him when the wire is free.

Another matter intimately affecting the prosperity of the business is that of tariffs. It is very difficult to lay down any definite principle or to find a common standard by which the tariffs of different localities may be compared. We want more statistics. We cannot learn much from the mere ratio of the number of subscribers to the number of inhabitants unless we have full information as to the commercial and social conditions of the town.

These are only a few of the many questions which might be raised, but it is believed that they will well repay examination.

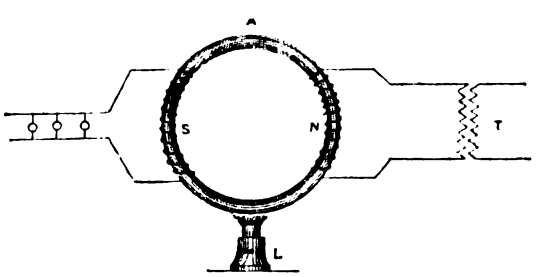
ACHESON'S CALELECTRIC GENERATOR.

From time to time during the last twelve months we have noticed in the American journals reports of the most startling character relating to the discoveries of Mr. Acheson, of Pittsburgh, in a field which he has, so far, made wholly his own, and which he terms "calelectric generation." Up to the present time, however, we have been unable to come across any sufficiently clear or exact description of what Mr. Acheson has actually accomplished—or believes himself to have accomplished—to be worth reprinting. But at length we have an account in the *Electrical World* (New York) which leaves us in no further doubt on the latter score, and accordingly we print it below. In view of the demand which this article makes upon the faith of the English reader, it may be well to add that Mr. Acheson is held in no small esteem in electrical circles in the States, and although his "explanation" of the phenomenon is not quite up to European standards, yet his good faith is, we believe, beyond question. The *Electrical World* article is as follows:—

The work of Mr. Edward G. Acheson, of Pittsburgh, on the conversion of heat directly into magnetism and electricity is already known. Briefly stated, the method devised by Mr. Acheson consisted in causing heat-lines to traverse an electric conductor and produce a magnetic whirl, cutting the heat-lines and thereby converting the heat energy into electric energy.

Since commencing this work, Mr. Acheson has elaborated various other methods analogous to the first, one of which is shown diagramatically in the accompanying figure. The arrangement consists of an alternating-



current generator, with a converter so arranged that the iron core may be put under the influence of heat, a thermometer being included in the secondary coil of the converter as a current and heat indicator.

With an apparatus arranged as above indicated and having a given current at T, with the source of heat removed, there is registered on the thermometer a certain value representing the electric energy traversing the coil S and its circuit. But when the source of the heat L is placed in proper position to cause the heat-currents therefrom to impinge upon the mass of magnetic material, with the source of energy at T the same, it is found that the thermometer shows an increased value for the electric energy in the coil S.

Mr. Acheson explains this action on the assumption that if heat can be converted directly into electricity, it should also be possible to produce magnetism from heat energy, and if this is the case the application of the heat energy to the magnetic material will result in an increased magnetic state of the magnetic mass, which will react upon the coil of wire surrounding the mass, and produce therein an electric current, which will represent a part of the energy of the heat. While Mr. Acheson has not yet been able to clearly demonstrate this fact, he has demonstrated fully that the application of heat in the manner described does produce a material increase in the current flowing through the coil S and its connections.

NATIONAL ELECTRIC LIGHT ASSOCIATION, U.S.

Storage Battery Traction.*

BY J. BRACKEN.

It has been customary for speakers on storage batteries to begin their discourse by apologising for their subject. That day has gone by. The storage battery has no longer any apologies to make.

My purpose at first was to give a detailed account of the progress of storage battery traction by going back to 1881, when the first storage battery car was run and following up the history of improvements from that time to the present. But I have found it impossible to get full and reliable data as to the work accomplished in Paris, in England, or in this country. I wrote to almost all the companies and individuals who have been engaged or are now engaged in storage battery traction to send me full accounts of their experiments and work; but I regret to say that only one responded to my request, and that was Mr. A. H. Bauer, who gave me a very interesting account of his experiments with his storage battery car in Baltimore, in 1885-86. I am therefore compelled to confine my remarks to my own observation of storage battery traction. I will not weary you with threadbare information. I once heard a judge tell a loquacious lawyer that he must assume the Court knew *some* law. I will assume that you have a pretty general acquaintance with the storage battery in lighting and in traction; but there may be some features, chiefly commercial, that have not come under your observation. My observations cover a period of over three years, during which time the company with which I am associated has directed its talents and energy to the development of storage battery traction. You all, no doubt, appreciate the difficulty of the task—not alone difficulties inherent in the system itself, but difficulties arising from the scepticism and lack of sympathy, I regret to say, of a very large majority of the electric community. We all know how much scepticism on the part of street railway men has had to be overcome in electric traction of every kind. It has taken a great deal of hard work—of missionary work—on the part of electrical engineers and inventors to bring about present results. But this is not to be wondered at; for there is nothing harder to accomplish than to supersede an old and well-established system. The horse car had plodded along and gathered strength and influence just as it had gathered fares. That influence was wide spread and almost all-pervading, for there is hardly a town on this great Continent that has not its horse-car line. The horse-car system has been spreading for about fifty years, and when it came to be in full and undisputed possession of the field, can it be wondered that those men who had the hardihood to attempt to supersede it should be regarded with more or less suspicion—should be looked upon as pretenders—especially when you consider that the method which they propose to employ was electricity; that dark and mysterious science as many people, even now, regard it.

Now, the first experiments made with electric cars were calculated to increase this suspicion and to throw disfavour on electric traction; for it is a characteristic of inventors to be so far carried away by their enthusiasm as to commit great indiscretions in carrying on experiments in public, which really should be conducted in private. It was on this account that the early experiments of Daft, in 1883, and of other well-known electric engineers in succeeding years, while they created wonder, did not beget confidence. I may say without any invidiousness that two years ago there was not a single electric car run in this country that proved anything more than possibilities.

There were probably two dozen cars being run at that time by the overhead wire system, but so unsatisfactorily that people who went to see them came away shaking their heads with distrust. Now, all this distrust has disappeared and electric traction has grown so fast, that to-day there are no less than one hundred street car lines in this country that are either running their cars by electricity, or are in the course of introducing the system. Electric traction has beyond all doubt come to stay; as the French say, it has arrived. But the large cities are threatened with the cable. The storage battery proposes, however, to challenge its supremacy. . . . .

When the storage battery first became known in a practical and commercial form by the experiments of Plate in 1859, scientists foresaw for it a great future, and when corporations were formed later on to exploit and introduce the storage battery, the people of Europe, influenced by what might have been considered the extravagant praises of Sir William Thomson and other well-known scientists, put an enormous amount of capital into storage battery enterprises. Almost all of those enterprises, however, proved to be commercial failures, first because the exploiters were ahead of their time, and secondly because the public were led to expect more than the storage battery, in its then crude form, would do.

There probably have been few things more difficult to accomplish than to bring the storage battery to its present stage of commercial value. Notwithstanding all that had been written about its nature and characteristics, its treatment both in its manufacture and use has, until very recently, been purely empirical. That stage, fortunately, has been passed; so that, with intelligent care, the storage battery to-day is not only a valuable adjunct in lighting, but is becoming a very prominent factor in traction.

The advantages of storage battery traction, assuming that it is practical and economical, are too obvious for me to occupy your time in recounting.

The obstacles in the way of success of the system are largely if not wholly overcome. The chief of these was the *handling* of the batteries. That was the most difficult and the last obstacle to be overcome by us. Two improvements removed these difficulties. First, the *flexible connector*, which enables us to couple up or remove cells with great rapidity, and secondly, the battery rack, occupying a floor space of 24ft. by 7ft. on each side of the car, wherein we can store a sufficient number of batteries to run from 10 to 20 cars, according to its location. This rack represents stall room for 150 horses, or, say, 6,000 square feet. I regard this rack as the greatest improvement hitherto made in storage battery traction. By its aid we remove the batteries from a car and replace them by another set in from two to three minutes; indeed our cars on Madison-avenue—and I may say here that we begin to-day to run ten (10) in daily service—have to leave the station on six (6) minutes' headway. In the afternoon trips there is but six minutes interval between their arrival and departure; and they all receive their batteries from the same rack. When the car enters this rack, its panels are dropped down on either side, and thus form bridges over which the batteries are withdrawn from and replaced in the car. While this change is being made, a competent person inspects the regulators of the cars; the motors, gearing and connections are only inspected once a day, and that at the end of the day's work. You will thus perceive that the great bug-bear of how to store the batteries is no longer an element in storage battery traction.

From my observation of our recent work on Fourth and Madison-avenues, now that we are running a number of cars and under very unfavourable conditions as to station room and the like, I am led to believe that the storage battery car is as free, if not freer, from accident, as cars that are

* Paper read at the meeting of the above Association, held at Niagara Falls, August 7, 1889.

Digitized by Google

run by the overhead system. The motors are, I think, subjected to less trying conditions, owing to the fact that the E.M.F. is always uniform. The batteries give neverout on the trip. It is impossible for them to do so, as they leave the station with 35 electrical horse-power hours stored in them, and do not consume quite 12, in the round trip of 12 miles. We have never short-circuitted the battery in service. When the current required exceeds 150 amperes, the battery is automatically cut out. When we used rigid connectors, we frequently had difficulty with their breaking, and the flexible connector has, until recently, give us some trouble, from time to time by jumping out of position while the car is in service; but with our recent improvements disconnection of the batteries while the car is in service is now rendered almost impossible. For several months past we have had absolutely no trouble from our regulators. In any event there are two on the car, so that if one should fail the car may be operated from the other end. You will thus perceive that the likelihood of accidents or breakdowns is reduced to a minimum. Our first standard car has run in three months over 6,000 miles, and carried over 80,000 passengers, never having missed but one-half a trip in that time, and that arose from a bent axle. It has never had an accident or stoppage of any kind while in service. Do not be sceptical at the assertion when I tell you that we have never spent a dollar on that car in the way of repairs or alterations.

At this stage you will naturally ask, how about the life of the battery? I answer that from our observation we have nothing to fear on that score. We only ask a life of six months from the positive plates; we know that they will last very much longer than that. The chief reasons why the short-livedness of a storage battery has been so much talked about and feared is that it has until recently cost so much to manufacture the battery. Now the material for your battery you have to buy, in a great measure, but once, for the reason that the discarded battery can be made over new. The raw material in two sets of battery, capable of running a car 120 miles a day, costs, exclusive of the containing jars, about $300. Have you machinery and devices requisite for manufacturing this raw material cheaply into a battery? If you have, you need have nothing to fear on the score of economy. It will cost $4,000 to purchase enough horses to run a 16 foot car 120 miles a day; it will cost about $1,500 to purchase enough battery to do that work. The batteries can be maintained for about one-half what it costs to maintain the horses, and by maintaining I mean replacement as well as feed. This I know for a fact. Can we then have any further doubt as to the relative economy of storage battery traction.

Our cars on the Madison and Fourth-avenue line take one electrical horse-power hour per mile. The road has some long gradients. The grade at Centre-street is over 4½ per cent., and 600ft in length.

The cost of motive power for a car day of 75 miles we estimate at $3·40, as against $7·50 for horses. Five dollars for 75 miles ought to cover the cost in winter. By motive power we mean the cost of energy at two cents per horse-power hour, and $700 per annum for maintenance of batteries and motors. To those who may think that two cents per horse-power is a low estimate, we would say that power has been offered to us in New York, to be delivered to us at our station at the price above-named. In towns outside of New York offers have been made to supply current at lower figures. The more level the roads the cheaper obviously will be the cost of motive-power. This is more particularly true of the storage battery which, in excessively steep and long grades, becomes heated. The chemical energy instead of exhibiting itself in the form of electrical energy, exhibits itself in the form of heat, with consequent injury to the battery. Our cars will ascend very steep grades; but we do not deem it economical to attempt grades of more than 6 per cent., and they must be short at that rate. But there are few roads offering more and steeper grades than the road we are now operating on in New York. Each car has two sets of battery. A set is easily charged in about two-thirds of the time the other is in service. No time is lost in charging, as the battery is automatically put in circuit with the dynamo as soon as it is withdrawn from the car. Now that we have a complete group of cars in service in New York, and hope to follow those by another 10, we shall all know more about storage battery traction at our next annual meeting.

LIGHTNING, LIGHTNING CONDUCTORS, AND LIGHTNING PROTECTORS.*

(Concluded from page 384.)

Appendix I.

Theory of B *Circuits, of "Alternative Path" Experiments, and of Side Flash.*

Consider a couple of jars connected to the terminals of a machine by their inner coats and to a wire circuit by their outer coats (Fig. 1).

They form an ordinary circuit with a capacity inserted equal to the semi-harmonic mean of the two jars separately, and an air gap of adjustable width at A; and the maximum difference of potential producible in it is determined by the distance of the A knobs. When the discharge occurs, a current flows of course equally round the whole circuit, but the peculiarity is that up to the instant of discharge the B portion of the circuit is at a uniform potential. If a gap exists in B also, as it well may, the terminals of the gap may likewise be at the same potential up to the instant when the rush occurs. The discharge will, as usual, be oscillatory unless the resistance of the whole circuit be too great; and the period of oscillation will be approximately $2\pi\sqrt{(L S)}$, where S is the capacity of the two jars in series.

Now number the coatings of the two jars as shown in the diagram, and write down their electrical condition before and during the discharge spark at A:—

	Plate 1.		Plate 2.		Plate 3.		Plate 4.	
	Charge	Potential.	Charge	Potential.	Charge	Potential.	Charge	Potential.
Before discharge	+Q	+V	−Q	−V	−Q	0	+Q	0
After ¼ period	0	0	0	0	0	−V	0	+V
After ½ period	−Q	−V	+Q	+V	+Q	0	−Q	0
After ¾ period	0	0	0	0	0	+V	0	−V
After a whole period	+Q	+V	−Q	−V	−Q	0	+Q	0

and so on, with gradual damping (the damping being omitted in the table for simplicity).

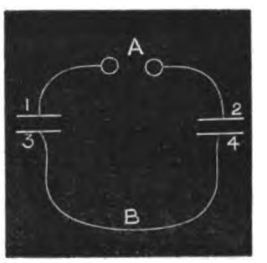


Fig. 1.

Thus, then, between the ends of the B wire exists at regular intervals almost the whole difference of potential which is able to jump the air gap at A. Strictly speaking, the difference of potential is rather less than that corresponding to the A gap; thus the equation to the current at any instant is accurately

$$C=\frac{V_0}{p L}e^{-\frac{R}{2L}t}\sin p\,t,$$

where V_0 is the initial difference of potential corresponding to the A spark, and where

$$p=\sqrt{\left(\frac{1}{LS}-\frac{R^2}{4L^2}\right)}.$$

Now, if L_1 is the portion of the whole self-induction which corresponds to the B length of wire (*i.e.*, subtracting from the whole L the part belonging to the A wire), and if R_1 is the resistance of the B wire, its impedance is $\sqrt{((p L_1)^2+R_1^2)}$; and while a current, C, is flowing through it, the difference of potential between its ends is therefore $\sqrt{((p L_1)^2+R_1^2)}\,C$.

Now the current flowing through attains its maximum value one-quarter period after the A spark has commenced, *i.e.*, in a time

$$\frac{\pi}{2p};\left(\text{more exactly, in a time }\frac{1}{p}\tan^{-1}\frac{2pL}{R}\right);$$

and inserting this in C we get the maximum possible strength of current, viz.:—

$$C_1=\frac{V_0}{pL}e^{-\frac{\pi R}{4pL}}.$$

Hence the maximum possible difference of potential between the ends of the B wire is

$$V=V_0\,\frac{\sqrt{\left\{L_1^2+\left(\frac{R_1}{p}\right)^2\right\}}}{L}\cdot e^{-\frac{\pi R}{4pL}};$$

that is, a certain fraction of V_0, the fraction being

$$\frac{\text{total impedance of B wire}}{\text{inertia impedance of whole circuit}}\times\text{damping during }\tfrac{1}{4}\text{ period.}$$

Very often a sufficient approximation to this is

$$\frac{L_1}{L}e^{-\frac{\pi R}{4pL}};$$

and if the wires are thick and short, or non-magnetic, and the

* From the *Journal* of the Institution of Electrical Engineers, being the reply of Dr. Lodge to the discussion on "Lightning, Lightning Conductors, and Lightning Protectors."

Digitized by Google

capacity big, the damping during the first quarter of a period is often so small that merely the fraction $\frac{L_1}{L}$ will do sufficiently well.

So then, if a supplementary pair of tapping knobs be connected to the ends of the B wire, as shown in Fig. 2, and if their distance be adjusted to be $\frac{L_1}{L}$ths of the A distance, a spark is liable to pass at these knobs.

This is what I call a B spark, and the spark gap affords an alternative path to the B wire, or *vice versâ*.

There is no need to tap off the *whole* of the B wire. Any portion, however small, will serve, provided the appropriate value of L_1 is used. The length of the B spark measures the difference of potential needed to propel the current through the portion of wire which is thus tapped. Of course, if a B spark actually *occurs*, it introduces disturbance; the knobs should be set so that it just fails.

There is one thing not here explicitly stated, but which has to be taken into account in calculating the value of R, and that is the loss of energy by radiation. With small jars and circuits this loss is very great, and it increases the value of R enormously. See a Paper of mine in the forthcoming July *Philosophical Magazine*. With big jars and circuits it may be safely omitted; the experimentally observed B spark will agree with calculation. But with small jars, if it be omitted, the observed B spark will be always less than the calculated.*

In this way a measure of the damping due to radiative dissipation of energy can immediately be made.

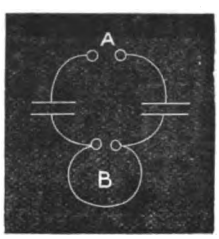

FIG. 2.

The observation of Mr. Wimshurst about the neutral point indicates at once that this theory also gives the length of side flash obtainable from the wire. Let any part of the B wire be put to earth, or let its natural neutral point be found, then the V calculated as above for any other point gives the length of side flash obtainable from that point to earth.

Side flash is in fact a special case of the alternative-path experiment. With a symmetrical wire like this, everything insulated and the jars equally charged, the neutral point is naturally the middle. But with a lightning conductor the lower end is to earth more or less completely, hence from the actual bottom of the wire no side flash should be obtainable. One always will be obtainable, however, owing to the impossibility of making a non-resisting earth of infinite capacity. Higher up, the length of side flash obtainable must be its length at the bottom plus the V corresponding to height of point tried. The maximum side flash is obtainable from the top of the wire. The strength or energy of the spark depends, of course, on the capacity of the body receiving it (if insulated); being $\frac{1}{2}$ S V^2, when V is calculated as already said. If it be an earthed body, then the whole discharge divides itself between the two paths, according to the laws of divided current appropriate to these conditions.

In testing a conductor, a spark should be given to the top, and the length of side spark obtainable at the bottom should be observed. All else can be calculated, except in so far as there may be defects in the visible portion of the rod.

APPENDIX II.

Resistance and Impedance for Frequencies Comparable to a Million per Second.

If $\frac{p}{2\pi}$ is the frequency of current conveyed by a wire of length l, and of ordinary resistance r, made of a substance of permeability μ; then its resistance to currents of excessively high frequency is

$$R = \sqrt{(\tfrac{1}{2} p l \mu r)},$$

hence the resistance of soft iron is immensely higher than that of any non-magnetic metal.

The self-induction under the same circumstances is

$$L_0 + \frac{R}{p},$$

where L_0 refers solely to the space surrounding the conductor.

The inertia portion of the impedance is*

$$p L_0 + R,$$

of which the first term is far the bigger at high frequencies, even for iron, unless the wire is very thin.

The total impedance is

$$\sqrt{(p^2 L_0^2 + 2 p L_0 R + 2 R^2)},$$

of which, again, the first term usually far eclipses the others.

Numerical Examples.—1. Let the length l, of conducting rod be 10 metres, its diameter 1 centimetre, and let it be bent into the form of a circle (if it be straight, there will be but little difference); take $\mu = 1$ for copper, or 900 for iron; specific resistance, 1,600 square centimetres per second for copper, or 7 times this for iron; and let $p = 2\pi \times 10^6$ per second.

Then, whatever the substance of the conductor,

$$L_0 = 12{,}000 \text{ centimetres};$$

while the common resistance,

$$r = \begin{cases} \cdot 002 \text{ ohm for copper.} \\ \cdot 014 \text{ ohm for iron.} \end{cases}$$

Hence the effective resistance is

$$R = \begin{cases} \cdot 08 \text{ ohm for copper.} \\ 6 \cdot 3 \text{ ohms for iron.} \end{cases}$$

The inertia portion of the impedance is,

$$p L_0 + R = \begin{cases} 75 \cdot 4 + \cdot 08 = 75 \cdot 5 \text{ ohms for copper.} \\ 75 \cdot 4 + 6 \cdot 3 = 82 \cdot 0 \text{ ohms for iron.} \end{cases}$$

The total impedances are practically the same—viz.,

$$\begin{cases} 75 \cdot 5 \text{ ohms for copper.} \\ 82 \cdot 0 \text{ ohms for iron.} \end{cases}$$

2. If, instead of taking a rod 10 metres long, we consider a length 100 metres long, of the same thickness, these quantities become:—

$$L_0 = 162{,}000 \text{ centimetres.}$$

$$r = \begin{cases} \cdot 02 \text{ ohm for copper.} \\ \cdot 14 \text{ ohm for iron.} \end{cases}$$

$$R = \begin{cases} \cdot 8 \text{ ohm for copper.} \\ 63 \cdot 0 \text{ ohms for iron.} \end{cases}$$

$$\text{Inertia part of impedance} \begin{cases} 1{,}003 \text{ ohms for copper.} \\ 1{,}066 \text{ ohms for iron.} \end{cases}$$

$$\text{Total impedance} \begin{cases} 1{,}003 \text{ ohms for copper.} \\ 1{,}067 \text{ ohms for iron.} \end{cases}$$

3. Lastly, for a wire 100 metres long, but 1 *millimetre* in diameter, the values would be

$$L_0 = 208{,}000.$$

$$r = \begin{cases} 2 \text{ ohms for copper.} \\ 14 \text{ ohms for iron.} \end{cases}$$

$$R = \begin{cases} 8 \text{ ohms for copper.} \\ 630 \text{ ohms for iron.} \end{cases}$$

Inertia part of impedance,

$$p L_0 + R = \begin{cases} 1310 + 8 = 1{,}318 \text{ ohms for copper.} \\ 1310 + 630 = 1{,}940 \text{ ohms for iron.} \end{cases}$$

$$\text{Total impedance} \begin{cases} 1{,}318 \text{ ohms for copper.} \\ 2{,}040 \text{ ohms for iron.} \end{cases}$$

All this supposes the frequency to be determined independently of the conductor considered, and to remain the same; but as the conductor increases in length it has a tendency to decrease the frequency; and that is the meaning of my sentence in Section 28, to which Major Cardew objects, "and of any moderate length, such as 100 yards or less (not many miles)."

I ought to say that the here calculated values for R do not take into account at all the loss of energy by radiation. This will always go to increase R, often very perceptibly, sometimes enormously. I will go into this further in some other place.

These examples illustrate sufficiently well the comparative behaviour of iron and copper under well-marked and frequently-occurring conditions. I have chosen the frequency of a million a second, because I have shown reason for believing that it is not at all unlikely to apply to the circumstances of lightning; the capacity discharged per flash, and the self-induction of its path, being neither of them very big.

* See *The Electrician* for 21st June 1889.

* At first sight it may seem as if I were making a mistake in having an R term in the purely inertia part of the obstruction, but it is quite right. This term R happens to represent exactly the magnetisation of the substance of the wire, so far as its outer skin is magnetised.

Digitized by Google

But while we are about it, it is instructive and quite easy to write down the values for some considerably lower frequencies; not for slow frequencies such as alternating machines give, the theory for them is more complicated, but the simple theory will do for, say, 10,000 complete periods per second. The result will be distinctly different. No longer does inertia constitute the whole of the obstruction for iron, though it still does for copper; and for iron it constitutes the largest part.

Frequency, 10,000 per second.		Resistance, R.	Inertia part of Impedance ($p L_0 + R$).	Total Impedance.
		Ohms.	Ohms.	Ohms.
10-metre rod 1 cm. thick	copper.	·008	·762	·762
	iron ...	·63	1·384	1·52
100-metre rod 1 cm. thick	copper.	·08	10·11	10·11
	iron ...	6·3	16·96	18·1
100-metre wire 1mm. thick	copper.	·8	13·9	13·9
	iron ...	63·	76·1	98·8

The depth penetrated by the current into the substance of the wires, is definite at a given frequency, unless the wire is too thin to leave a central margin, and is independent of the diameter of the wire; at least for these high frequencies. It is easily calculated with fair approximation, thus the sectional radius of the wire being a:—

$$\frac{2\pi a\, da}{\pi a^2} = \frac{r}{R},$$

whence da, the depth effectively penetrated by the current, or the thickness of conductor practically made use of, is—

For the million per second frequency { in copper $\frac{1}{15}$ millimetre; in iron $\frac{1}{180}$,,

For the ten thousand per second frequency { in copper $\frac{1}{15}$ mm.; in iron $\frac{1}{18}$,,

It may be after all, therefore, that I am wrong in saying that rod is anything approaching as good as tape for conductors. It is nearly as good in respect of mere impedance, but whenever there is any chance of the wire being melted, then tape is far better. Rod ought to be apt to have its skin burnt off, unless the central core has time to exert any cooling action by sharing the heat.* But it is because I doubt whether decently substantial conductors are in any real danger from heat that I have asserted the advantage of greater surface to be but small.

I wait, however, for an expression of authoritative opinion from the President on these points.

Appendix III.

On the Melting of Conductors.

The list of fused conductors at the end of the Lightning Rod Conference Report, Appendix J, is very short, but short as it is it includes things not quite free from serious misleading. Over and over again it has been truly asserted that wherever there is an arc or a flash to a conductor damage is likely to be done. Terminals which have to receive the flash should always be thicker than the wire which has only to conduct it. This must be regarded as very ancient and orthodox, as well as very true. I now run through the short list of damage and analyse it. The table is headed "List of Metals Melted."

1. "Copper rod, ·35 inch diameter." This was an upper terminal, tapering from one-third of an inch diameter at the *base* to a point, and only 9½in. long altogether. This terminal was "nearly all melted."

2. "Copper rope, ·31 inch diameter, at Nantes." Callaud, "Traité," p. 89.

3. Rope, *said* to be ·7 inch diameter, at Carcassone. Callaud, "Traité," p. 89.

These I will refer to directly. They were not fused, but broken, or eaten into, or otherwise "burnt by use."

4. "Iron rod, ·2in. diameter." This was a few inches melted from the *point* of an upper terminal, and some of the links of a *chain*.

5. "Brass rod, ·2in. diameter." This was a tapering terminal, 10in. long, of the given diameter at the *base*, and it was only melted for one-fourth of its length.

The implied *statement* in the report is, therefore, that a brass rod ¼ of an inch in diameter was melted. The *fact* is, that 2½ inches was melted off a sharp brass point! Fortunately in this case, and in case 1 also, the body of the report itself contains the material capable of overthrowing this misrepresentation.

6. "Copper rod, *perhaps* ·13 inch diameter." This was a common bell-wire, and it was legitimately destroyed, but still it protected.

That is the whole list, and it amounts to nothing more than a bell-wire, and to cases 2 and 3, the account of which I now proceed to translate from the treatise of M. Callaud. The Carcassone case is one of the two Mr. Symons quotes in his remarks (the other is case No. 4, above). It is the only one that sounds improbable, and the evidence for it seems to me weak; but I leave readers to judge. The evidence for the Nantes cases, such as they are, is perfectly good.

Extract from "Traité des Paratonnerres," par A. Callaud, p. 89:—"The conductor of the Church Santa-Croix at Nantes was a cable of red copper, a centimetre in diameter; it was formed of seven strands, each consisting of seven wires, the wires being one millimetre thick. I was witness of a storm and of violent flashes which traversed it, and it showed no trace of deterioration. This size can therefore be permitted, though it seems to me slight. The cable which existed before that of which I speak, also of red copper, was found broken by a flash and damaged over a part of its length; il avait eight millimetres. I know of conducting bars, five millimetres, which a single storm has deteriorated and eaten into in a way that ten years of rust would hardly accomplish.

"M. Viollet-le-Duc, whose words I have had the honour of quoting, has seen at Carcassone some cables of lightning conductors burnt by use. Ils avaient 18 millimetres. 'In this town,' he tells me, 'storms are frequent—daily, in certain seasons.' In such a case the size of 18 millimetres will be then insufficient."

This last is a most vague account. The material is not specified, nor is it perfectly certain whether the 18 millimetres refer to the diameter, or whether it means that it consisted of 18 wires, each a millimetre thick. Evidently, however, M. Callaud supposes it to mean the diameter, and most likely it does. But why in the plural? And does "burnt by use" mean anything more than that some of the thin wires were burnt or fused together, or that the cable was oxidised superficially?

Considering the exceptional character of the testimony, if understood in the Lightning Rod Conference sense, it is a pity it is second-hand.

Appendix IV.

On Conditions under which Points can be Preferentially Struck in Case B.

Referring to Mr. Wimshurst's observation of the effect of the sign of top-plate, the following is an extract from an April note book kept by my assistant:—

"Large sphere (or dome), knobs, and point, arranged between two plates so as to be equally struck by a B spark. The plates are connected to the outer coats of the two small or pint jars, whose inner coats are connected to the machine, between whose termina's occurs a moderate A spark.

1st. *With the top-plate positive.*

Distances of	Dome	2·5	centimetres.
	Large Knob	3·6	,,
	Small knob	3·8	,,
	Point	3·8	,,

2nd. *Top-plate negative.*

Distances	Dome	2 5	centimetres.
	Large knob	3·0	,,
	Small knob	3·7	,,
	Point	8·0	,,

Lengthening the A spark makes the distance at which the point is struck less."

The following measurements have been made quite recently, large jars being used, but the vigour of the rush being diminished in some cases by making the A spark (*i.e.*, the distance between the machine terminals) quite short.

Two gallon jars similarly connected, instead of the pint jars. Objects arranged between plates to be easily and about equally struck, as before. First, with the A spark 1 centimetre long.

Top-plate negative.

Distances from top-plate of	Large knob	1·2	centimetres.
	Small knob	1·4	,,
	Point	2·4	,,

Top-plate positive.

Distances of	Large knob	1·5	centimetres.
	Small knob	2·2	,,
	Point	2·3	,,

* The specimens exhibited by Mr. Preece, of copper wire incipiently fused by lightning internally, are interesting. They may have been fused by the dead-beat tail of a current; the outside cooling most rapidly. They *look* as if they had been hottest inside, and if so an explanation is needed; but they are not likely to upheave the foundations of electro-magnetism.

Digitized by Google

Lengthen A spark to 5 centimetres—

Top-plate negative.

Distances of { Large knob ..... 3·4 centimetres. Small knob ..... 3·5 ,, Point ..... 3·9 ,,

Top-plate positive.

{ Large knob ..... 4·0 centimetres. Small knob ..... 4·2 ,, Point ..... 3·9 ,,

Repeat with A spark *about* 5 centimetres, but the B distances made greater.

Top-plate positive.

{ Large knob ..... 5·4 centimetres. Small knob ..... 4·7 ,, Point ..... 4·7 ,,

Top-plate negative.

Distances unaltered, and all are struck occasionally as before, but the small knob gets struck rather more often than the others, and the large knob rather less often.

Hence, it is clear that under circumstances when the rush is really *impulsive*, the difference between positive and negative top-plate, which Mr. Wimshurst called attention to, does not exist. It nly exists in so far as the rush is gradual.

WATER-SPRAY INFLUENCE MACHINE.*

BY GEORGE FULLER.

This machine is for obtaining directly from a fall of water a supply of electricity of a high potential. It consists of four similar parts arranged symmetrically round a central vertical support (Fig. 1.), and each division has the following members :—

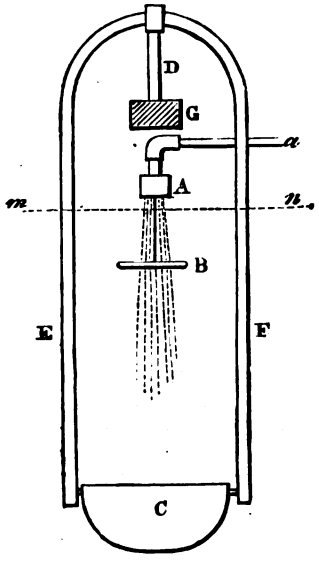

Fig. 1.

A nozzle, A, in connection with a head of water by means of a pipe, *a*.

A ring, B, of brass or copper wire placed vertically below A, and through which the water descends when the machine is in action.

A vessel, C, placed below B to receive the water that has passed through the ring.

A brass tube, E F, between the ends of which the vessel C can turn about a horizontal axis.

An insulating glass rod, D, to the top of which the tube E F is attached, and with the lower end fixed in a part of the frame of the machine G.

A sectional plan on *m n* (Fig. 2) shows the connection between the four divisions, which are numbered I., II., III., IV. The wire ring of section I. is in electrical connection with the receiver of section IV. Similarly the ring of II. is connected with I., the ring of III. with IV., and that of IV. with I.

* Paper read before the Physical Society.

K is a central column for supporting four arms of the machine to which are fixed the insulators D.

The discharge of electricity is taken between conductors in connection with II. and III.

The nozzle is a flanged brass box, the bottom of which is perforated with small holes through which the water descends. It is fixed by a number of small bolts and nuts through its flange to a brass plate fixed to the supply pipe *a a* (Fig. 3), and the joint is made watertight by a vulcanised india-rubber ring. A piece of fine linen covers the top of the box to strain the water before it reaches the small holes, as it was found that the water was either stopped or diverted by small particles unless this precaution was taken. The holes, which are circular, have a diameter of $\frac{1}{100}$"; as it was found that when holes $\frac{7}{1000}$" were used the water was so much dispersed by the working of the machine that a great part of the water ceased to fall into the receivers. This great dispersion also injured the insulation, and besides this it was extremely difficult to keep these holes free.

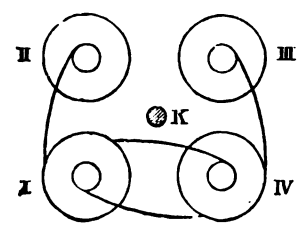

Fig. 2.

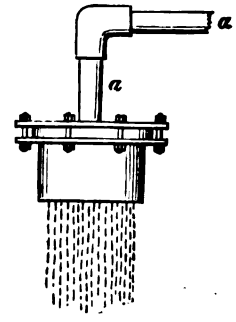

Fig. 3.

With regard to the number of holes : In the nozzles of sections I. and IV. there are six arranged in a circle of $1\frac{1}{4}$" diameter ; for those of sections II. and III., either a pair with twelve holes each in a circle of $1\frac{1}{4}$" diameter, or with eighteen holes in a circle of $1\frac{3}{4}$" diameter.

The rings are made of brass or copper wire of about $\frac{1}{8}$" diameter. The inside diameter of the rings used with the nozzles with six and twelve holes is $2\frac{1}{4}$", and with the eighteen holes $2\frac{3}{4}$".

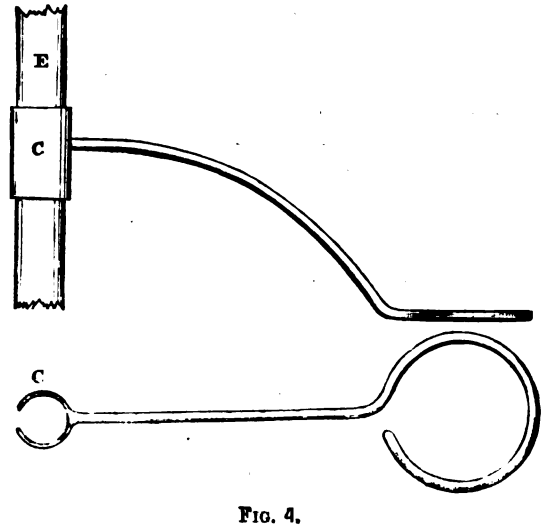

Fig. 4.

The wire of each ring is continued and fixed to a clip of split brass tube, C (Fig. 4), which slides upon the brass tube E or F. This enables the depth of the ring below the nozzle to be adjusted, which is of importance, as the greater the head of the water employed the greater must be the distance between the two, as the ring should be fixed at the point where the small streams of water break up into spray. The receiving vessel C (Fig. 5) may be of glass or metal, as the former material, from its constant state of moisture whilst the machine is working, seems to conduct the electricity as effectually as the latter. In the author's model they were at first of glass, but one of them having been broken they were replaced by receivers of zinc. The receivers are supported by pins, *p*, *p* which are soldered to them at one end, whilst their free ends rest in holes drilled in E and F. To make the receiver self-acting they are hung so that when a leaden weight, *w*, is fixed, as shown in sketch, the vessels being empty, they would turn in the direction of the arrow (Fig. 6) if they were not prevented by s ops soldered to them which press against E and F ; but when the receivers are nearly full of water, their balance is such that they

Digitized by Google

turn in the opposite direction and so empty themselves. The four receivers are made to turn towards the axis of the machine and to deliver the water into a metal bath, which for continuous action should be connected with a drain.

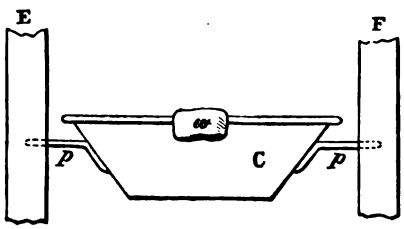

FIG. 5.

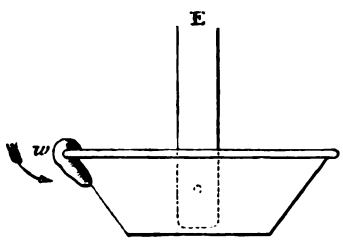

FIG. 6.

The following are some of the dimensions of the author's model (Fig. 7) :—

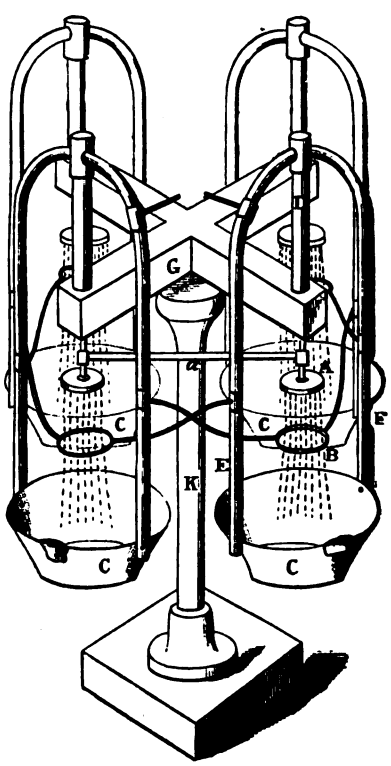

FIG. 7.

Zinc receivers 8″ diameter at the top.
Brass tube E and F $\frac{3}{8}$″ diameter.
Glass rod D $\frac{3}{4}$″ diameter, with an insulation of 4″.
From the rim of C to the lower surface of A, 9$\frac{1}{4}$″.
From the rim of C to the underside of stand, 1′ 1″.
From centre to centre of insulators D across the centre line of instrument, 1′ 11″.

The Electrical Action of the Machine.

An instrument made of only sections I. and IV., with their rings connected with their receivers, as shown above, will charge itself ; and the difference of potential of the two receivers may be such that sparks $\frac{1}{2}$in. long may occasionally pass between them, though more usually $\frac{3}{8}$in. is the longest that can be obtained with a head of water of about 23ft. With this arrangement, after every discharge the potential of the rings is nearly equalised ; whereas in the machine with four sections, I. and IV, keep up the difference of potential of the rings of II. and III.

With respect to the action of the machine, the author, whilst giving the considerations from which it was constructed, must leave to the electrician to determine whether they have anything to do with the true explanation of the phenomena. The water, at the point where it is divided into drops by the resistance of the air, is electrified by induction from the rings, the former being in connection with the earth through the unbroken water of the stream ; and the action seems similar to that employed in Sir W. Thomson and Prof. Silvanus Thompson's water-dropping accumulators. That such is the case appears to follow from the fact that, if the rings are either placed much above or much below the level where the water breaks into spray, the machine ceases to work. When the rings are at their proper level there is an additional action ; for the particles that are inductively electrified are split up into numberless minute particles, some of which are so fine that they float about in the air and do not fall into the receiver. And it is this breaking up of the water into minute particles that the author thinks may account in part for the effect produced ; for when a number of spheres that have been electrified unite into a mass of less surface, their potential in the latter state is higher than in the former.

Another point which the author thinks must be taken into consideration is the speed with which the particles move through the ring, as it was only when he experimented with a fall of some feet instead of inches that he obtained a potential high enough to produce sparks. With a very slow speed the attraction of the ring is too strong for the water, so that it at last, as in Sir William Thomson's apparatus, bends against it. That the division of the drops into minute spray plays a part in the action of the machine seems to be shown by the fact that sparks of the same length, in the same state of the atmosphere, have been obtained from it when the velocity of the water has been very much diminished. The sparks, as a rule, have not been so numerous per minute, but the water has been divided into finer spray. At times, even with half the delivery of water, the same length of spark has been obtained.

One experiment the author has made in which the spray was not obtained by the action of gravity, but by a steam "atomiser," as it is called. The water and steam passed through a copper wire ring 1$\frac{1}{2}$″ diameter, connected with one of the receivers of an apparatus made up of sections I. and IV., as above. The nozzle was $\frac{5}{8}$″ from the ring and 5$\frac{5}{8}$″ from the receiver. Sparks $\frac{1}{4}$″ in length were taken freely from the receiver, which is a better result than has been obtained with a fall of water of some 23ft. What was very observable in this case was the very small amount of water used, a small teacup-full being passed over in some five or six minutes ; and the author has recorded in his notes that the experiment was made on a very wet day.

Adding to the number of jets does not seem to increase the power of the machine, either in quantity or potential, at all in proportion to the number added ; though the action of an electrical machine is so eccentric that it is difficult to be certain of this, for at times the nozzle with 18 jets has given much better results than the one with 12 jets.

It has been stated that in the machine as made the rings are 1″ larger in diameter than the circle of the jets, and it is found that they give a better result than when larger rings are used ; but in some experiments with a small flow of water a ring 3$\frac{1}{2}$″ diameter gave as a large a spark as one of 1$\frac{1}{2}$. In the dark electricity is often seen to fly off from the rings, the water on them being made into pointed-shaped drops.

The machine in its present form is by no means powerful, as with a small Leyden jar attached to it the longest spark has hitherto been 1$\frac{1}{8}$″, the head of water being about 23ft. The state of the atmosphere has very great influence on the working of this machine, for though in all states of the weather electricity will be generated, it requires a fairly dry atmosphere to give 1″ sparks.

It may be mentioned that the machine has only been tried in a small bath-room, which is a very unfavourable place for electrical experiments ; and it perhaps is worth mentioning that on one occasion sparks were only obtained when window and door were open and the machine was in a thorough draught.

To what extent the power of the machine may be increased it is difficult to predict ; but the author thinks that the experiment with the atomiser points to high velocity in the water, combined with minute subdivision, as the direction in which any future attempts should be made.

An Electro-Medical Vaporiser.—An ingenious apparatus has been devised by a Dr. Telschow for the purpose of vaporising solid medicaments, and it has already rendered great service in connection with throat complaints. The apparatus consists of an india-rubber syringe, traversed by a piece of platinum wire. This wire is covered with the powder medicament, and a strong current of electricity is sent through it. The wire becoming incandescent the powder is vaporised and is carried by the current of hot air in the required direction.

THE BOARD OF TRADE RULES FOR OVERHEAD WIRES.

The following regulations have just been issued by the Board of Trade :—

In these regulations the words, terms, and expressions to which by the Electric Lighting Acts, 1882 and 1888, meanings are assigned, shall have the same respective meanings, provided that in these regulations—

"Energy" means electrical energy, and for the purposes of the Electric Lighting Act, 1888, and these regulations, electrical energy shall be deemed to be an agency within the meaning of the word electricity, as defined in the Electric Lighting Act, 1882.

"Conductor" means an electric wire or line used for the supply of energy.

"Aerial conductor" means a conductor which is placed above ground and in the open air.

"Low pressure conductor" means a conductor in which the difference of electric potential either between that conductor and earth or between that conductor or any part thereof and any other conductor on the same poles or supports does not exceed 300 volts, if the supply be on the continuous-current system, or the equivalent of 150 volts if on the alternating-current system. A difference of potential on the alternating-current system shall be deemed to be the equivalent of a difference of potential on the continuous-current system, when it produces an equal heating effect if applied to the ends of a thin-stretched wire or carbon filament.

"High-pressure conductor" means a conductor in which the difference of electric potential as above described is greater than that of a low-pressure conductor.

Regulations.

1. An aerial conductor in any street shall not in any part thereof be at a less height from the ground than 20ft., or where it crosses a street 30ft., or within 6ft. of any building or erection other than a support for the conductor, except where brought into a building for the purpose of supply.

2. Every aerial conductor shall be attached to supports at intervals not exceeding 200ft. where the direction of the conductor is straight, or 150ft. where this direction is curved, or where the conductor makes a horizontal angle at the point of support.

3. Every support of aerial conductors shall be of a durable material, and properly stayed against forces due to wind pressure, change of direction of the conductors, or unequal lengths of span, and the conductors and suspending wires (if any) must be securely attached to insulators fixed to the supports. The factor of safety for the suspended wires shall be at least 6 and for all other parts of the structure at least 12, taking the maximum possible wind-pressure at 50 pounds per square foot. No addition need be made for a possible accumulation of snow.

4. Every support, if of metal, shall be efficiently connected to earth, and if of wood or other non-conducting material, shall be protected from lightning by a lightning conductor fastened to the support along its entire length, and projecting above the support to a height of at least six inches, such lightning conductor being efficiently connected to earth.

A support shall be efficiently connected to earth when it is connected to metallic mains for water supply outside of buildings, or, where these are not available, to a mass of metal having a total surface of at least four square feet, buried to a depth of at least three feet in moist earth, provided that in either case the connecting conductor must possess a mechanical strength, and offer a passage to electrical discharges, equal to that of a strand of seven No. 16 galvanised iron wires.

5. Every aerial conductor shall be protected by efficient lightning protectors of pattern approved by the Board of Trade.

6. Where any conductor crosses a street the angle between such conductor and the direction of the street at the place of such crossing shall not be less than 60 degrees, and the spans shall be as short as possible.

7. Where an aerial conductor is erected so as to cross any other aerial conductor or any suspended wire used for purposes other than the supply of energy, precautions shall be taken by the owners of such crossing conductor against the possibility of that conductor coming into contact with the other conductor or wire, or of such other conductor or wire coming into contact with such crossing conductor by breakage or otherwise.

8. The maximum working current in any aerial conductor shall not be sufficient to raise the temperature of the conductor in any part to such an extent as to materially alter the physical condition or specific resistance of the insulating covering, if any, or in any case to raise such temperature to a greater extent than 30deg. of Fahrenheit's thermometer, and efficient automatic means shall be provided which will render it impossible for this maximum working current to be by any accident exceeded to the extent of 25 per centum, even for short intervals of time ; and special care shall be taken that the cross sectional area and conductivity at joints is sufficient to avoid local heating, and that the joints are protected against corrosion.

9. Every high-pressure aerial conductor must be continuously insulated with a durable and efficient material, to be approved by the Board of Trade, to a thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulation must not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000. This insulation must be further efficiently protected on the outside against injury or removal by abrasion. If this protection be wholly or partly metallic it must be efficiently connected to earth, so, however, as not to cause undue disturbance to other electric lines or works by electrostatic induction or otherwise.

10. The material used for insulating any high-pressure aerial conductor must be such as will not be liable to injurious change of physical structure or condition when exposed to any temperature between the limits of 10°F. and 150°F., or to contact with the ordinary atmosphere of towns or manufacturing districts.

11. The insulation resistance of any circuit using high-pressure aerial conductors, including all devices for producing, consuming, or measuring energy, connected to such circuit, shall be such that should any part of the circuit be put to earth, the leakage current shall not exceed $\frac{1}{15}$th of an ampere in the case of continuous currents, or $\frac{1}{10}$th of an ampere in the case of alternating currents. Every such circuit containing high-pressure conductors shall be fitted with an indicating device which shall continuously indicate if the insulation resistance of either conductor fall below the conditions required by this Regulation.

12. Every aerial high-pressure conductor shall be efficiently suspended by means of non-metallic ligaments to suspending wires, so that the weight of the conductor does not produce in it any sensible stress in the direction of its length, and the insulated conductors and suspending wires, where attached to supports, shall be in contact only with material of highly insulating quality, and shall be so attached and guarded that in case they break away it shall not be possible for them to fall away clear of the support.

13. In the case of aerial conductors carrying alternating currents, the two conductors constituting the line and return for any circuit shall be run parallel with each other, and at a distance apart not exceeding 18in.

14. The owner of every aerial conductor shall be responsible for the efficiency of every support to which such conductor is attached, and every support shall be efficiently marked with such mark indicating the ownership of the conductor as the Board of Trade shall approve.

15. Every aerial conductor, including its supports and all the structural parts and electrical appliances and devices belonging to or connected with such conductor, shall be duly and efficiently supervised and maintained by or on behalf of the owners as regards both electrical and mechanical conditions.

16. An aerial conductor shall not be permitted to remain erected after it has ceased to be used for the supply of energy, unless the owners of such conductors intend within a reasonable time again to take it into use.

17. Every aerial conductor shall be placed and used with due regard to electric lines and works from time to time used or intended to be used for the purpose of telegraphic communication or the currents in such electric lines and works, and every reasonable means shall be employed in the placing and use of aerial conductors to prevent injurious affection, whether by induction or otherwise, to any such electric lines or works or the currents therein.

18. (*a*) A notice describing every aerial conductor erected or used for the supply of energy shall forthwith, upon receipt of these regulations, be served upon the Postmaster-General, together with a plan showing the mode and position in which such conductor is erected.

(*b*) The Postmaster-General, upon consideration of such notice and plan may require such alteration in the position or mode of erection, or mode of use of such conductor, or compliance with such other condition as he may think fit, having regard to the protection of the electric lines or works of the Postmaster-General, and any failure on the part of the body or person owning or using, or entitled to use, the said conductor to comply with such requirements shall be deemed to be a non-compliance with these regulations.

(*c*) Any notice required to be served upon the Postmaster-General under these regulations may be served by being addressed to him and left at, or transmitted through the post to, the General Post Office, London, and any notice required to be served on the body or person owning or using, or entitled to use, any aerial conductor may be served by being addressed to such body or person and left at, or transmitted through the post to, their or his office or last known place of address.

CORRESPONDENCE.

ELECTRIC TRACTION ON THE BRUSSELS TRAMWAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your Note on page 368 in last week's issue, and the report of M. Michelet, it occurred to me that it is hardly fair to compare the working costs of three electric cars with those of a large and well organised system of horse cars. You state that "the cost of working the same line with horses is estimated at 25 centimes per car kilometre, and the cost of the electrical system, *exclusive* of maintenance of stationary machinery, royalties to the inventors, interest upon the capital, and depreciation of plant, but including the cost of maintaining the accumulators, comes out at the same figure." According to the report, the cost of renewing accumulators amounted to 9 centimes per car kilometre; the maintenance of car motors and the transmission apparatus was actually 5·74 centimes, leaving for steam power, &c., 10·25 centimes, in order to bring the total to the sum of 25 centimes per car kilometre. Converted into English equivalents we should have for—

Renewals of accumulators ...	1·44	pence	per	car mile.
„ motor and gearing	·92	„	„	„
Steam power.....	1·64	„	„	„
Total.....	4·00	„	„	„

This leaves no provision for depreciation of steam-power plant and dynamos. You have rightly pointed out that these cars are running over steep gradients, and that the lines are badly laid. I think there are few tram lines more difficult than those of the Rue de la Loi and the Rue Juste Lipse. Three cars cannot be as economically worked from one station as ten or twenty cars, whether by animal or by mechanical power, and the gain in economy is especially marked in the cases of electric and cable traction, where a whole system is fed from one large engine.

The manufacture of accumulator plates in Brussels is still carried out on a comparatively small and expensive scale, which renders the item of plate renewals very costly. Moreover, the type of plate used is not conducive to durability, as has been proved over and over again. Traction cells can now be made involving a depreciation of less than one penny per car mile, which would reduce this item on the Brussels tramcars by at least 30 per cent., and leave a good margin of profit to the manufacturer and patentee. One need not fear being thought hypercritical in pointing out that the maintenance of the car motors and gearing at Brussels is excessively high, viz., ·92d. per car mile. English cars run on an average 70 miles per day; this item would thus amount to £98 per annum per car, equal to about 50 per cent. on the gross value. Such figures reflect sadly upon the design and workmanship in the mechanism, and I am inclined to assume that M. Michelet included experimental work of some kind or another. Lastly, the balance of 1·64d. ought to cover amply the cost of fuel, attendance, maintenance, and depreciation of the engine, boilers, and dynamos at the charging station.

It seems to me that even with a very slight reduction in the above items of depreciation, but operating on a much larger scale (with economical engines and dynamos) the working costs of the Brussels electric tramway could be reduced to a fraction below horse traction, and with a more rational design there should be an economy sufficient to induce the Tramway Company to adopt electricity in preference to horses.—Yours, &c.,

A. RECKENZAUN.

London, August 19, 1889.

THE THEORY OF ALTERNATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of August 9th, you invite cricitisms on the experiments and views of Mr. Mordey on the construction and behaviour of alternators, more especially as to parallel working. Mr. Mordey's Paper contained some extremely interesting experiments, some very valuable results, several opinions which cannot exactly be called theories because no explanation was proposed, but no data of the constructive details of the machine which would enable any numerical test to be made of any explanation that study would suggest. Now the difference between the old ideas on alternators and the new ideas proposed by Mr. Mordey, is this: the old idea was that alternators can only run together in parallel provided that there is in the circuit of the armatures, or their connecting wires, self-induction and resistance, Mr. Mordey says the perfect alternator is that which has no self-induction and no resistance. (Some authorities, notably Mr. Kapp and Prof. Forbes have, I think, made a point of having self-induction of considerable magnitude as of prime importance, but this is not strictly any part of the older idea which really lays special stress on a certain ratio between self-induction and resistance, and not on their absolute magnitude.) Now, although Mr. Mordey has laid down this proposition, he has not, so far as I am aware, made any suggestion as to the process by which two such dynamos, as he contemplates, control one another, and only offers as a proof the results obtained by experimenting with an alternator, in which, though the absolute values of the coefficient of self-induction and the resistance are small, still they admittedly exist, and their ratio, so far as I understand, is almost precisely what Dr. Hopkinson's formulæ predict as the most satisfactory value,* only that Mr. Mordey's coefficient of self-induction is still larger than the older ideas point out as desirable—that is, for a given output of machine his field-magnet requires further strengthening, and the armature turns diminishing. In the absence, therefore, of any experimental proof that two alternators will run in parallel without self-induction, and in the absence of any theory of why they should do so, the burden still lays with Mr. Mordey to prove that they will, and until that proof is afforded it appears to me that in view of the corroboration that Mr. Mordey's experiments give to the older idea, a certain scepticism as to the truth of his main proposition is allowable.

The fundamental axiom which rules all cases of running generators, either continuous or alternate, in parallel, is that the machine that leads (or accelerates) should take more load than the machine that lags (or is retarded). The older ideas give at least an explanation of how this result is produced in the case of two alternators in parallel with self-induction; but as yet Mr. Mordey has given no reason why, if there is no self-induction, the leader should have the greater load. What Mr. Mordey has done is this: he has shown experimentally that for efficient working in parallel we must work an alternator far below its maximum possible output, which Dr. Hopkinson's formulæ also indicates, and that this can only be done by keeping the internal resistance and self-induction small; he has not, I maintain, proved that they should both be absent, or that the ratio between them ought to have some value very different from that pointed out by Dr. Hopkinson. Neither has he proved that an alternator with iron in the armature cannot be made to satisfy the conditions of running in parallel as well as his own machine, whilst experiment shows that with properly designed iron-cored armatures all the experiments he described, including that of unequal volt generators, can be repeated with precisely similar results. I do not wish here to enter into any side issues suggested by some other experiments, but will conclude by asking "what experimental evidence or what theoretical reason is there, to suppose that two alternators, in whose combined armature circuit is no resistance and no self-induction, will run in parallel?"—Yours, &c.,

London, Aug. 19. LLEWELYN B. ATKINSON.

* Mr. Mordey states that the fall of potential of the alternator from light to full load is about double that due to the resistance of the armature alone, or the apparent resistance is twice the ohmic resistance, hence

$$\sqrt{R^2+\left(\frac{2\pi L}{T}\right)^2}=2R. \therefore R^2+\frac{4\pi^2L^2}{T^2}=4R^2. \text{ Hence } 3R^2=\frac{4\pi^2L^2}{T^2} \text{ and}$$

$$R=\frac{2}{\sqrt{3}}\frac{\pi L}{T}.$$

For Dr. Hopkinson's condition $R=\frac{2\pi L}{T}$ to be satisfied when the dynamos are coupled by leads of no resistance, the apparent R should be $\sqrt{2}\times$ the real resistance.

AN IMPROVED LIGHTNING PROTECTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* of last week, at page 375, we observe an attempt by Mr. A. R. Bennet to reinvent a well-known "Lightning Protector," combining points and fine-covered wire wound round an earthed cylinder, of which we have been the sole manufacturers for the last *thirteen* years.

A working model of the form of lightning protector was first brought to us by Mr. Andrew Jamieson (now Prof. Jamieson, of the Glasgow and West of Scotland Technical College) from

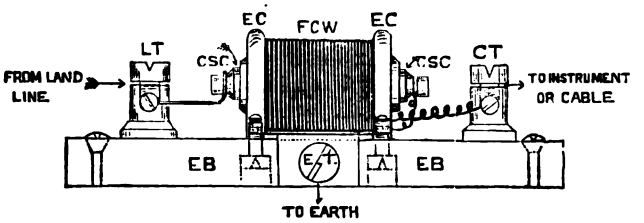

FIG. 1.—Jamieson s Lightning Protectors for Submarine Cables. (Side elevation.)

LT ..... Line terminal.	EC ..... Earthed cylinder screwed and insulated from CSC by
CT ..... Cable or telegraph instrument terminal.	EW..... Ebonite washer.
ET ..... Earth terminal.	EB..... Ebonite base.
CSC .... Central seriated cylinder.	FCW ... Fine covered wire.

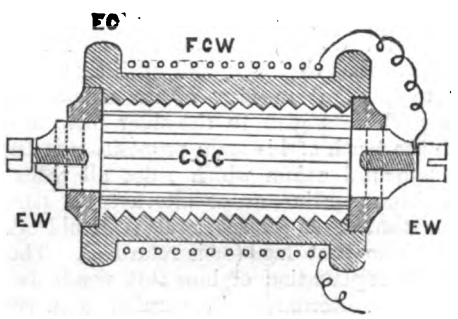

FIG. 2.—Jamieson's Lightning Protectors for Submarine Cables. (Longitudinal section through earthed cylinders.)

Brazil, in August, 1876. We have made and exhibited it in different forms at most of the large exhibitions, including the Glasgow International Exhibition last year, and we have sold them to the Eastern, Eastern Extension, the Western and Brazilian, the Direct Spanish, and other telegraph companies.

A very full description of this Protector was given by Mr. Jamieson, in a Paper read by him before the Society of Telegraph Engineers, at their meeting in November, 1876, to which we sent specimens (see *Proceedings* of this Society, Vol. V., pages 358 to 388, with a full sized drawing of the pattern we make specially for submarine cables).

We herewith enclose a tracing of this drawing (see Figs. 1 and 2), which we are not aware has been otherwise illustrated except in Wunschendorff's "Submarine Telegraphy" of 1888.

"Jamieson's Lightning Protector" combines three things in direct circuit with landline and cable or landline and telegraph instrument:—

(1). The fine points between line and earth plates or cross serrated cylinders.

(2.) Two or more straight fine platinum wires, which automatically come into circuit, the one after the other (so as to keep up telegraphic communication), until the last one fuses or the fine-covered wire coil gives way.

(3.) A fine-covered wire coil brought into intimate association with the earthed cylinder by being wound round the same (just as in Mr. Bennet's proposed plan), so that the self-induction of this coil may, as far as possible, assist in protecting the telegraph instrument or the cable from injury should (1) the points and (2) the fine platinum wire have failed to do so.

We have never had any report that this protector failed in its duty, but we would like to have Dr. Lodge's opinion upon this combination of points, wire, and coil.—Yours, &c.,

LATIMER CLARK, MUIRHEAD, AND CO. (Limited).

23, Regency-street, Westminster, S.W., Aug. 21, 1889.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The short article in your issue of 16th August on "An Improved Lightning Protector," might, I think, admit of a little discussion.

In the first place the writer announces that "experience shows that fusion of coils of fine wire by lightning almost invariably occurs at the commencement of the winding . . . penetration beyond the first layer appears to be altogether unknown." This may be the happy experience of the writer, but it is not the experience of a practical mechanic who for many years has had the repairing of many and various kinds of fine wire coils and of all kinds of lightning protectors. He has in most cases found the damage to have taken place in the layer next the iron core of the relay or the earthed metal core of the lightning protector, and in some few cases fusion has taken place near the middle of the coil, but *never* at the commencement of the winding.

The "improved" protector which the writer submits, is simply the discarded bobbin protector of the Post Office combined with the more or less generally discarded serrated plate protector, the former having been discarded, not because it "always" pro-

tected, but because it always broke down the circuit; and the latter, because it was found not to be so efficient as the plain plate protector. For one thing, the serrated protector must be carefully protected from dust; whereas the plain plate protector with thin mica sheet needs no protection.

Again, the replacing of the damaged coil, although simple enough in itself, would be too much for unskilled hands, and I expect telephone inspectors or linemen would be kept busy replacing them after a thunderstorm, as telegraph linemen were in the days when the Post Office used the bobbin protector.

The writer must refer to the telephone world when he says that the arrangement he proposes is novel. Cables in the Post Office service, and I expect in most cable companies, are, and have been, protected for a long time by a combination of, firstly, a plate protector; secondly, "the intimate association of fine wire with an earth plate;" thirdly, a vacuum tube; and lastly, next the cable a short piece of very fine platinum wire.—Yours, &c.,

W. NOBLE.

12,619. F. J. PATTEN. London. Improvements in and relating to dynamo electric machines or motors.

NEW COMPANIES REGISTERED.

JOHANNESBURG ELECTRICITY SUPPLY COMPANY (LIMITED).—Registered by Hollams, Sons, Coward and Hawkesley, with a capital of £250,000 in £1 shares. Object, to acquire and take over a concession dated February 28, 1889, in relation to the supply of electric light in Johannesburg and its suburbs, granted by the Government of the South African Republic, and to work and turn the same to account, and to carry on the business of an electric supply company generally. There shall not be less than three nor more than seven directors. The first are Sir Charles Metcalfe, Bart., Sir Douglas Fox, F. Henwood, A. P. Matheson and Colonel R. Thynne, C.B. Qualification £100. Remuneration, £2,000 divisible.

CITY NOTES, &c.

CHILI TELEPHONE COMPANY (LIMITED).—A prospectus of this company was issued last week. The capital of the company is £250,000, divided into 50,000 shares of £5 each. The directors are:—R. Raynsford Jackson, Esq. (National Telephone Company, Limited), chairman; Hon. F. Ernest Allsopp, 12, New Cavendish-street, W.; T. Greenwood, Esq. (Taltal (Chili) Railway Company, Limited). Bankers: Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C. The secretary (*pro tem.*) is Mr. Edmund Petley, and the offices are situatate 53, New Broad-steet, E.C. The prospectus states that the company has been formed for the purpose of acquiring and extending the property and business, in the Republic of Chili, of the West Coast Telephone Company, which is an American Corporation.

DEVON AND CORNWALL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—With the sanction of Mr. Justice Chitty a third and final return of capital, amounting to 3s. 4½d. per share, has been declared by Mr. H. T. Edwards, the official liquidator of this company, and is payable to the shareholders on any Monday at the offices of Messrs. James and Edwards, 66, Coleman-street, London, E C.

DISSOLUTION OF PARTNERSHIP.—The partnership between Mr. F. C. Phillips and Mr. F. G. Hart, trading as electrical engineers at 2, Victoria-mansions, Westminster, S.W, under the title of Phillips and Hart, has been dissolved.

FALCON ENGINE AND CAR WORKS.—An extraordinary general meeting of the shareholders of this company was held on Thursday last week at the offices, 39, Coleman-street, E.C., for the purpose of confirming resolutions passed on the 23rd ultimo, approving of the provisional agreement between the Falcon Car Company and a trustee for the company intended to be formed, to be called the Brush Electrical Engineering Company, for winding-up the company, and authorising the liquidators to carry into effect the agreement. Mr. Aymor H. Sanderson, who presided, formally moved the adoption of the resolutions. This was seconded by Mr. Duncan, and agreed to.

THE FOWLER-WARING CABLES COMPANY (LIMITED).—We are informed that the capital of this company was largely over-subscribed. Letters of allotment and regret have been posted.

THE MANGANESE BRONZE AND BRASS COMPANY.—At the ordinary general meeting of this company, held on Thursday last week, the directors proposed to pay a further dividend of 10s. per share, free of income tax, payable on 2nd September next, making, with the interim dividend paid in March last, 16s. per share for the year, and carrying forward £1,759.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended August 16, 1889, amounted to £4,334.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended August 16, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,935.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this company for the half-month ending August 15 amounted to £2,784, as compared with £2,629 in the corresponding period last year, a decrease of £245.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

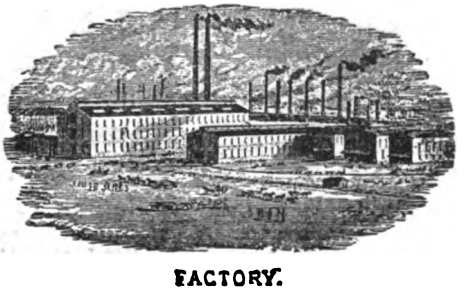
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 589.—Vol. XXIII. FRIDAY, AUGUST 30, 1889. Price Fourpence.

NOTES.

Nothing could have been more completely *apropos* or in better taste that the eulogy delivered by Sir William Thomson upon the work of the French electricians at the joint meeting of the Société International and our own Institution on Friday last. Sir William's own scientific methods are, indeed, widely different from those which characterise the French school of theorists, but his and our appreciation of their numerous triumphs is, doubtless, none the less thorough and sincere on that account. We none the less venture, in the interest of historical accuracy—and we think we need make no apology for so doing—to demur to one or two of the admissions which the President made in respect of French claims to priority in invention. Surely it is scarcely correct to say that Gramme was the first to construct a practical dynamo machine. Was not Gramme at the very time of his great invention of the armature that bears his name in the service of the Alliance Company? And was not this company then building the Wild machine—a machine which was so far practical that it had been adopted by the Trinity Board? To Gramme was due the epoch-making invention of an armature capable of yielding a quasi-continuous current, but there were practicable dynamos before his day. Again, Sir William yields to Duboscq the credit of having constructed the first automatic arc lamp, an honour which is generally conceded to Staite. Indeed, Prof. S. P. Thompson has, we believe, discovered that Duboscq's first specification for a patent was rejected on the ground of anticipation by Staite. To Davey and to Faraday the world owes the discovery of the principle of the arc light and of the dynamo, and if, as we honestly believe, to our countrymen also belongs the honour of first bringing these great discoveries into the region of practical utility, we cannot consent to lightly yield the claim.

The tenth meeting of the National Electric Light Association, at Niagara Falls, appears to have been of the usual successful character. The Papers, however, do not possess so much interest for English readers as those read at the last summer meeting. A considerable amount of time was devoted to the subject of execution by electricity, and the outcome of Mr. F. A. Wyman's legal memoir, and the subsequent lengthy discussion thereon, was a decision to petition against the new law to the General Assembly of New York, and a general protest against this "unnecessary degradation of the most useful natural agent that science has ever rendered available for the service of man."

In Mr. G. W. Mansfield's Paper on "Electric Railways," which we print elsewhere, there are some striking figures illustrating the very marked effect which the number of cars operated, gradients, and other local circumstances have upon the electrical horse-power required per car. Thus at Boston, Mass., the average electrical horse-power per car is 5·9, while at Richmond, Va., it is between 4 and 5, and at Lafayette only 2·5 according to Dr. Bell.

Our reply to Mr. Swinburne's further letter will be but brief, though we shall endeavour to make it clear. Our correspondent devotes the first portion of his letter to anathematising those people who misuse the term "self-induction," and in this we can most heartily concur, since our own conscience is absolutely clear. But with a degree of inconsistency which we are wholly at a loss to explain, Mr. Swinburne permits himself, in a succeeding paragraph, to employ the term to describe the reaction of the armature upon the (separately excited) field; this is, of course, a case of *mutual*, not self, induction. The issue is in this way somewhat obscured, but we think it can be made tolerably clear if we restate our own view in few words. Let there be an alternator driving a synchronising motor. Now, if the latter tend to get out of step the virtual current (as Mr. Swinburne calls it) immediately rises, thus increasing for the while the torque upon the armature of the motor. But the couple producing the torque is due to the reaction between the magnetic field of the armature and that of the field magnets. *Mr. Swinburne calls this the self-induction of the armature.* On the contrary, following orthodox usage, we have always spoken of the self-induction (or, to be more exact, the E.M.F. of self-induction) as being due solely to the change of current in the armature, being of course proportionate to the *rate of change*, and tending to oppose and delay such change. Hence we conceive Mr. Mordey to be wholly in the right when he says that the less the total self-induction in the circuit, the more perfectly will synchronism be maintained, because the more rapid will be the rise of current necessary to increase the torque and pull the armature of the motor into its proper position.

From what has just been said it is easy to deduce the corollary that the stronger the field of the motor the less will be the

Digitized by Google

energy wasted in maintaining synchronism. (This, by-the-bye, is the criterion by which we judge whether a machine will synchronise "equally well" under varying conditions. We mention it because Mr. SWINBURNE complains, perhaps justifiably, that "equally well" is a vague and unscientific expression.) The corollary above stated has been justified by experiment upon the Mordey alternator. Mr. SWINBURNE, upon the other hand, asserts that "an ordinary motor can be made to work well at full load *by weakening the field* till it is cophasedly synchronised." This is a result which, from the considerations which have just been advanced we should certainly not have anticipated. If, therefore, our correspondent is speaking from actual experimental knowledge, we must beg him to note that his result is not one upon which any general law can be based, unless he is first prepared to show why the Mordey alternator should prove an exception to the rule. This, however, is not the only statement made by our correspondent upon which the evidence in our possession leads directly to the contrary conclusion. To take one more instance only—but a quite fundamental one—Mr. SWINBURNE remarks that "the armature loss will increase as the load is decreased," and adds, "it is here that, I take it, I differ from Mr. MORDEY and from you." Certainly he does. We are also puzzled by our correspondent's statement that a machine can be run with the same field strength, first at 1,000 revolutions and next at 500 revolutions, and yet give the same number of volts. It would, we are sure, be instructive to learn how this is done.

SEEING, however, that we are so little agreed as to the data upon which the discussion is or should be based, it is manifestly useless to pursue the argument further. Our own position is, in fact, a little anomalous. Mr. SWINBURNE, it will be remembered, first drew the sword on us, and in defence we made use of certain experimental data, which, by the courtesy of Mr. MORDEY, have been placed in our possession, but which, pending the completion of the experiments, Mr. MORDEY does not wish to be fully made known. When we add that we have this week found it necessary to remove our editorial chair to the banks of the Seine, our motives for declining further controversy, at least for the present, will be readily understood. At an early date we hope, however, to see the combat renewed in more regular form, and with, we trust, some quite decisive result.

THE withdrawal of a large number of experienced telegraphists from the British Telegraph Service for employment in the Colonies and elsewhere seems to have given rise to some inconvenience at a few of the large provincial offices, notably at Cardiff, where, among other grievances now being aired in the Western newspapers, the staff are said to be suffering from overwork and incompetent juniors. If we may believe half of what we read, the public also are aggrieved by this state of affairs, and attention has already been drawn to the subject in Parliament. It is not denied that the clerks themselves are furnishing the material for these comments, and the reflection occurs to us why do they not agitate for the transfer of skilled operators from minor offices to fill the vacant posts? This, or the training of learners on the spot, is obviously the only means available for the purpose. We have noticed lately a praiseworthy move in the former direction as regards Postmasterships and the superintendents of Telegraph offices. There is really no reason why the same policy should not be pursued in the promotion of junior telegraphists—unless it be the objection of the local staff to have outsiders brought in from other offices.

ON the strength of the discovery that Postal and Telegraph profits combined yield a profit of nearly £4,000,000, Mr. HENNIKER HEATON urges his contention through the columns of *The Times* that all future profits in excess of this amount should be devoted to cheapening and facilitating postal and telegraph communication. As regards the Post Office, we need not stop to argue with him whether or not that department has a right to make a profit; for as it is the public, and not the department, that pockets the surplus, the public alone is entitled to spend it. But in respect to the Telegraph service, any disposal of its profits in the way suggested ought on strict business principles to be postponed for many years to come, seeing that the Telegraphs have been working at a loss for nearly twenty years past. When prospective profits have covered the accumulated deficits, we may then reasonably talk of lowering the rates. Meanwhile they are cheap enough for everybody but Mr. HENNIKER HEATON.

IN a recent number of the *Revue d'Hygiène*, M. MAKLOKOFF, of Moscow, relates his experiences of an "electric sunstroke" received at the Benardos Electric Welding Works at Kolomno, near Moscow, where it seems there is great difficulty in getting the workmen to work more than two hours a day, although they are paid very highly, on account of the injurious effect of the arc. The current at the Kolomno Works is obtained from 500 Planté accumulators, and an arc 5 centimetres long is produced. In order to obtain personal experience of the effects of an "electric sunstroke," and to be in better position to suggest a remedy, M. MAKLOKOFF exposed himself for about ten minutes to the light of the naked arc at close quarters. The outcome of this *experimentum in corpore vili* was, as will be seen, somewhat unpleasant. Two hours later a tingling sensation, combined with burning of the eyes and skin, was experienced. This was followed by a cold in the head and watering of the eyes, tumefaction, discoloration of the skin of the face, neck, and hands, chemosis of the eyelids, and photophobia. A feverish night. The following day increasing œdema. On the third day there was a deepening in the brickdust colour of the skin, which commenced to crack and peel. The chemosis and pains in the eyes disappeared when a secretion in the conjunctiva began to show itself. Subsequently there was desquamation of the skin, as in erysipelas. M. MAKLOKOFF attributes all these effects to the chemical action of the rays, and suggests that a glazed taffety veil, placed on a wicker headpiece, and provided with grey glass eyelet-holes, should be worn by those employed in the Benardos process and analogous operations.

Digitized by Google

The Metropolitan Electric Supply Bill.—The Royal assent to this Bill was given on Monday last.

Farnworth.—The Farnworth Local Board have instructed their Clerk to ascertain what steps should be taken by them in applying for an electric lighting Provisional Order.

Valencia.—Tenders have been invited in the Spanish papers for the electric lighting of Valencia. As the tenders have all to be in by the end of the present month, foreign competitors are practically excluded.

Bradford.—The New Midland Railway Station and Hotel, which are to be opened about the end of September, will be lighted by the electric light. The installation is being carried out by Mr. Langdon, the company's telegraph engineer.

The British Association.—The University of Durham has decided to confer honorary degrees upon several of the most noted members of the British Association during the visit of the latter to the north next month. The degrees will be confirmed at a special convocation.

The Electric Light at Rufford Abbey.—Lord Savile has had Rufford Abbey lighted throughout with the electric light, which has been introduced into every portion of the abbey, 400 lights, run off accumulators, being required. The whole of the work has been carried out by Messrs. Edmundsons, of Westminster.

Tenders for Telephone.—The Madrid *Gazette* contains a notice inviting tenders for the 30th proximo for the establishment and working of a telephone system in the island of Puerto Rico. The conditions provide for the payment to the Government of 6 per cent. of the total receipts.

A Magnet for Extracting Iron Filings.—Messrs. Frister and Rossmann, of Berlin, are making very powerful little magnets for the special purpose of extracting iron and steel filings from the eyes and skin of workmen engaged in ironworks. These magnets are of the horse-shoe shape, nickel-plated, with thin rounded poles, only a few millimetres thick.

The Lighting of Madrid.—The *Industria é Invencimes* says that a proposal for lighting Madrid with the electric light has been submitted to the Ayuntamiento by Señor Luis Capiston, in the name of the International Society for Lighting by Electricity. Señor Capiston offers to make a deposit of 100,000 pesetas, say £4,000, as guarantee for the due fulfilment of his offer.

Melbourne.—Although the evidence of experts at the recent inquiry into the cause of the destruction of the Bijou Theatre by fire discredited the idea that the electric lighting had anything to do with it, yet there seems, according to the local papers, to be a general desire that a public officer should be appointed to inspect all indoor installations before they are used.

Nantua.—A central lighting station was inaugurated at Nantua (Ain) last month, the motive power of which is obtained from a 40 horse-power turbine, driven by a 14ft. waterfall. The four dynamos are shunt-wound Gramme machines, giving 120 volts and 110 amperes. The three-wire system, with feeders, is employed, and the conductors are all run overhead.

Macclesfield.—At the last meeting of the Macclesfield Gas Committee, the Town Clerk submitted notices from two companies of their intention to apply for Provisional Orders for the supply of electric lighting in the borough. It was resolved that a special meeting be called to consider the advisability of the Corporation applying for a Provisional Order to supply electric lighting.

Huddersfield.—At a meeting of the Town Council on Wednesday last week it was resolved to make application to the Board of Trade for a Provisional Order giving power to the Corporation to provide and supply electricity within the borough. The Yorkshire House-to-House Electricity Company has announced its intention of applying for a Provisional Order for this town.

The Edinburgh Exhibition.—A deputation from the Executive Council of the Exhibition is at present in Paris, and arrangements have been made for the transmission to Edinburgh of a number of exhibits in the Exposition Universelle. Mr. Edison has been interviewed, and expressed himself much interested in the Exhibition, and he has consented to act as one of the vice-presidents.

Electric Light on the Midland Railway.—For some months past several of the Midland Railway Company's trains between St. Pancras and Manchester have been furnished with the electric light. After a lengthened trial, during which the great improvement in the ordinary train light has been made manifest, the company have decided to extend the light to their local trains. Already one or two experiments have been made in carriages running between Manchester and Stockport.

Sales by Auction.—The sale of the business of the Jensen Electric Bell and Signal Company, which was announced in our last issue, is fixed for Wednesday next. Messrs. Wheatley Kirk, Price and Goulty are also instructed to sell early in September the business of Mr. Lawrence Oppermann, of the Crown Works, Amhurst-road, Hackney. The sale by auction of the plant of the Basingstoke Iron Works, is also announced by Mr. Davison. Full particulars of these sales will be found in our advertisement columns.

An Electric Light Inspector for Liverpool.—The Watch Committee of the City Council had before them on Tuesday the seven selected candidates for the new office of electric light inspector for the city. Owing to the fact that there were no less than 47 applicants the matter has taken some time to settle. The Committee decided to recommend the Council to appoint Mr. C. H. Yeaman, assistant electrician to the Ward Electrical Car Company, London. The salary attached to the office is £160 per annum.

The Belgrano (Buenos Ayres) Gas Bill.—This Bill, to which we referred in our issue of July 19th, received the Royal Assent on Wednesday. The Chairman of Committees in the House of Lords had some difficulty about altering the memorandum of the company so as to enable it to embark on a business, namely, electric lighting, totally distinct from that for which it was originally incorporated. In order to have the matter thoroughly sifted, a Committee of members of both Houses was appointed, and the difficulty was overcome.

Friern Barnet.—At a recent meeting of the Friern Barnet Local Board, a report was presented in reference to the question of electric lighting of the district. It stated that a communication had been received from an electric light company who were prepared to light the district with 28 lamps of 43 candle-power, at a charge of £5 per annum for each lamp; the cost of erecting the necessary machinery and appliances being £1,360. The expense of running the cable underground would be £200 more, the length of the cable being 1½ miles.

Newcastle.—The Newcastle and District Electric Lighting Company and the Newcastle Electric Light Supply Company have received intimation that the terms of their license for lighting Newcastle have now been practically settled with the Board of Trade. The companies therefore expect to be in a position to commence the laying of the main cables almost immediately. The machinery and plant are now well advanced, and the companies intend to push forward the work of laying the cables vigorously so as to be able to supply current to customers before the end of next month.

Proposed Electric Railroad between Lanark and Hamilton. It is stated that a private company has been formed with the intention of constructing an electric railway from the town of Lanark to Hamilton, along the valley of the Clyde, the motive power to be obtained from Stonebyres Linn, one of the series of the Falls of Clyde. This is the broadest and most powerful of the Falls, the descent being nearly 80ft. The object is to afford the people of Lanark a more direct journey to Glasgow *vid* Hamilton than by way of Carstairs Junction. The distance between Lanark and Hamilton is about 15 miles.

Mr. Edison in Paris.—Mr. Edison was entertained on Thursday evening last week at the Hôtel Continental at a banquet given in his honour by the directors of the Compagnie Continentale Edison. Among the guests invited were Mr. Whitelaw Reid, United States Minister, M. Tirard, M. Janssen, of the Institute, the Postmaster-General, MM. Antonin Proust, and Jules Claretie. On Monday Mr. Edison was entertained by the *Figaro*, and on Tuesday evening, as will be seen in our Con-

Digitized by Google

gress Notes, a reception was given in his honour at the Exhibition by the British Commissioners.

Bishop Stortford.—At the last meeting of the Local Board three tenders were received for lighting the town, viz., Defries Oil Lamp Company, the Bishop Stortford Gas Company, and the Laing, Wharton and Down Construction Syndicate. The Gas Company tendered at £3. 5s. per lamp per annum. The Electric Light Company were willing to enter into a five years' contract to light 220 lamps of 20 candle-power each at a cost of £770 per annum, or £3. 10s. per lamp. A long discussion took place on the subject, and eventually it was decided to accept the Gas Company's tender.

Montreal.—On the first of August the streets of Montreal were for the first time wholly lighted by electricity. The Royal Electric Light Company fulfilled the terms of their contract, and 753 arc and 346 incandescent lights were lighted all over the city from shortly after eight p.m. to daybreak. The light has given general satisfaction, although the distribution of the lamps has been the cause of several complaints. In order to avoid as much as possible complaints about lights being out, 14 men (six on foot and eight on horseback) have had districts assigned them, so that in case of a lamp failing to burn it may be attended to as speedily as possible.

A Monster Casting.—An unusually large casting took place at Messrs. Wm. Beardmore and Co.'s Parkhead Forge on Friday afternoon last. Over 70 tons of metal was run into a mould sunk 23ft. into the ground, to form a shaft for a dynamo being constructed for the London Electric Supply Corporation. The casting is of Siemen's steel, and when cold will be hollowed to a diameter of 12in. When finished it will weigh about 32 tons. This is the second shaft cast by the Messrs. Beardmore for the London Electric Supply Corporation, and they have a third still to supply. The casting was in every way successful, and a shaft of excellent quality is expected.

A New Method of Preparing Wooden Battery Boxes.—It has long been a subject of complaint with regard to wooden battery boxes, says *La Lumière Electrique*, that in spite of internal and external coats of varnish they always begin to warp and leak after a certain time. With a view of remedying this defect the following process has been recently tried, it is said, with very satisfactory results :—The boxes are dried and placed in a closed vessel, which is then exhausted. The protecting liquid is next allowed to run in, and when the boxes are well covered air is admitted, and the pressure of the atmosphere drives the varnish right into the pores of the wood, rendering it highly impermeable.

New Books.—Messrs. J. and A. Churchill announce that they will publish in September an important work on Fuel and its Applications, by Mr. E. J. Mills, F.R.S., and Mr. F. J. Rowan. It will be the first volume of a large work on Chemical Technology of which Mr. C. E. Groves, F.R.S., will be the general editor, and which will be founded on one written by Richardson and Ronalds, familiarly known as "Knapp's Technology." Messrs. Mills and Rowan's work on fuel is in reality a new work, in which the applications of fuel to arts and manufactures as introduced by the most modern discoveries is given to the scientific world. The volume is profusely illustrated.

A Cable between Guatemala and the United States.—According to the *Revista Telegrafica*, the Government of Guatemala has concluded an agreement with Mr. McNider, for the establishment of several submarine cables between that country and the Antilles, Venezuela and the United States. The cables are to be in working order within two years' time, and an annual revenue of £5,000 is guaranteed by the Government. Official messages are to be transmitted at a reduction of 33 per cent. upon the ordinary tariff, and the contractor has bound himself to supply the Government of Guatemala with a daily *résumé* of all foreign news of importance for the sum of £20 a month. The tribunals of the Republic of Guatemala will alone be competent to adjudicate upon any differences that may arise between the contractor and the Government.

Obituary.—Prof. Elias Loomis, whose death is announced from New York, was one of the most distinguished physicists of the United States. He was born at Wellington, Connecticut, in 1811, and was educated at Yale College. In 1834 Prof. Loomis made hourly observations for sixteen hours per day, extending over fourteen months, of the declination of the magnetic needle. In 1836-7 he spent a year in Paris attending the lectures of Arago, Biot, and others. On his return he became Professor of Mathematics and Natural Philosophy in Western Reserve College, Ohio, where he remained until 1844. He also observed the dip of the magnetic needle at over 70 stations spread over 13 States, and extending from the Atlantic to the Mississippi River. In 1844 he became Professor of Natural Philosophy in the University of the City of New York, which chair he continued to fill until 1860. He then became Professor of Natural Philosophy and Astronomy in Yale, which appointment he held until his death. Prof. Loomis was the author of a series of mathematical and scientific text books, of which more than 500,000 copies were sold, and some of which have been translated into Chinese and Arabic.

Non-Magnetisable Alloys.—C. A. Paillard has recently drawn attention to the valuable properties of some of the alloys of palladium, and advocates their use in the manufacture of non-magnetisable watches. The composition of four alloys has been ascertained, and the author has examined their respective properties. An alloy consisting of palladium 60-75, copper 15-25, and iron 1-5 per cent., is really formed by mixing half the palladium with the copper and iron, and fusing the mixture with borax and powdered charcoal. The remaining palladium is then added, and the alloy fused and poured into moulds. A cheaper alloy, containing palladium 50-75, copper 20-30, and iron 5-20 parts, is recommended for common watches and certain parts of the works. An alloy similar in composition to the former, but containing 3-10 of silver and 1-5 per cent. nickel, with a small percentage of gold and platinum, is not affected by atmospheric changes, and its elasticity is not influenced by temperature. This alloy is also less magnetic than the two described above. If the percentage of silver be increased, and a corresponding diminution in the amount of palladium to 45-50 per cent. be made, a very good alloy is obtained, which is especially characterised by its great hardness.

Life of Arc Light Carbons.—In an interesting thesis on the length of life of arc-light carbons, contributed to the organ of the Cornell University, Mr. Louis B. Marks says :—The question has been asked in what manner and to what extent the size of the carbon affects the result in a current of given strength, covering, of course, in the general question of conductivity, the all-important results of light and life? The conclusion is now drawn from a multitude of experiments that, with carbons of the same manufacture and type, the life of the carbon varies directly with its diameter and inversely with its resistance. Thus the life of a 1in. brush carbon having an actual diameter of ·986in. and a resistance of ·061 ohm is, according to test, 26·15 hours. According to the law above stated, the life of a $\frac{5}{8}$in. brush carbon having an actual diameter of ·618in. and a resistance of ·0735 ohm would be by calculation 13·62 hours. When put to test this carbon burned 13·64 hours. Those systems in which a small current and a long arc are used are considered as high-tension systems, and those in which a large current and a short arc are used as low-tension systems. It has been found that, generally speaking, a moulded carbon is superior for high-tension and a forced carbon for low-tension systems.

Telegraphic and Telephonic Statistics.—According to a recent note in our well-informed contemporary, *La Lumière Electrique*, the total length of the telegraph lines of the world amounts to 557,064 miles, made up as follows :—Europe 216,490 miles, America 163,642 miles, Asia 46,800 miles, Australasia 24,204 miles, Africa 12,060 miles. To these must be added 950 submarine cables, 774 of which are laid in European seas, and have a total length of 3,200 miles, while the remaining 176, with a length of cable of 85,850 miles, belong to companies. The service of these lines is carried out by 160,000 offices. The telephonic statistics of the various countries of the world are as follows :—The United States 739 exchanges and 158,712 subscribers, Germany 164 exchanges and 31,325 subscribers, England 122 exchanges and 20,420 subscribers, Sweden 137 exchanges and 12,864 sub

Digitized by Google

scribers, France 28 exchanges and 9,487 subscribers, Switzerland 71 exchanges and 7,626 subscribers, Russia 36 exchanges and 7,589 subscribers, Italy 28 exchanges and 6,183 subscribers, Belgium 4,674 subscribers, Austro-Hungary 4,200 subscribers, Norway 21 exchanges and 3,930 subscribers, Holland 9 exchanges and 2,872 subscribers, Spain 2,218 subscribers, Denmark 1,837 subscribers, Portugal 2 exchanges and 890 subscribers. The town with the largest number of subscribers is Berlin, with upwards of 10,000, followed by New York, which has 6,900, Paris with over 5,000 and London with just that number.

Leicester.—At the meeting of Leicester Town Council on Tuesday, the Gas Committee recommended the Council to apply for a Provisional Order authorising the Corporation to supply electricity for public and private purposes within the borough. Councillor Lennard, in moving the adoption of the report, said that four companies had given notice of their intention to apply to the Board of Trade for an Order to supply the town. The Gas Committee had to consider what was the best thing to do for the town. It would not be right that they, as the lighting authority, should put themselves in the path of progress. Three courses were open to them. They might have selected any one of the companies, and have consented to an Order being granted to it. They might have opposed the application, or they might take powers themselves. With a view of preventing the monopoly of a single company or the friction which would be certain to arise between two or more companies, the Gas Committee finally decided to recommend that the Corporation should obtain powers. Mr. Lennard then detailed the courses open to them after the Order was obtained, and contended that if they acquired the right themselves they would get better terms out of the rival companies, if they felt inclined to trust the work to one of them, than if they allowed the companies to get the Order themselves. But the best thing for the public in the long run would be that the Corporation should work the whole affair themselves. They were not acting in a "dog-in the-manger" spirit, but *bonâ fide*. Mr. Lennard concluded by expressing a hope that they would not be unduly forced into producing electricity. The report was adopted *nem. con.*

Electricity from Heat.—In a thesis recently read at the Cornell University, Mr. G. D. Shepardson refers to the different methods for transforming the latent energy of fuel into electrical energy. The high efficiency of most electrical transforming devices and the ease of obtaining heat from electricity indicate, in his opinion, the possibility of some electrical method of getting cheap power from coal to excel the 10 per cent. efficiency of the steam-engine. The different methods fall into two general classes accordingly as they work by a changing temperature or by a constant difference of temperature in different parts. The first includes pyroelectric crystals, which are hardly adapted for commercial generation of electricity, and pyromagnetic motors and generators. A provisional theory for the latter gives a maximum thermodynamic efficiency of ·016 on one hypothesis, or of 0·000,000,005 on another, the former being the more probable. The second class is represented principally by the thermopile, whose efficiency is impaired by the conduction of heat from the hot to the cold junction, the highest theoretical efficiency for any combination yet tried being 0·12, while the highest actually attained and published is 0·0054. The thermopile is compared to a galvanic cell whose electrodes touch within the cell, the external effect being almost nullified by local action. Clamond has partially avoided this fault in recent types (1886), said to surpass all others in efficiency. By substituting an electrolyte for one metal of a thermopile, the efficiency is greatly increased and different gases have been introduced into the circuit with advantage. Attempts have been made, with indifferent success, to substitute carbon for the zinc of a galvanic cell, and to use the burning fuel as one electrode of a battery. One method uses the increased solvent power of liquids with rising temperatures. The most recent method is to increase the output of an alternating current transformer by heating the secondary coil. On the whole, the prospect is held by Mr. Shepardson to be encouraging as obtaining cheap power by the direct conversion of heat into electricity.

The Effect of Placing a Ball and Point in a High-Tension Alternating-Current Circuit.—A peculiar phenomenon which was first observed by Mr. E. G. Acheson has recently been investigated at the Cornell University. It bears a close relation to certain experiments of Mr. Wimshurst which will be within the recollection of our readers (see *The Electrician*, May 24, p. 70), and which was observed at a still earlier date by Faraday himself. The phenomenon referred to is as follows:—If a ball and a point be connected one to each pole of a source of alternating E.M.F., and also to the terminals of the galvanometer, a deflection as if from a direct current, will be observed in the galvanometer. It was found that, to get the effect, a high E.M.F. was necessary, and that the point must be brought so close to the ball that an arc forms between the two, and this arc drawn out to certain length, depending on the E.M.F. used, and on the resistance in the galvanometer circuit. The arc was shown to be intermittent, corresponding with the alternations, and to conduct apparently much more readily from the point to the ball than *vice versâ*, so that a very large excess of total current is in the direction from point to ball. A galvanometer placed directly in series with such a ball and point would show, therefore, a marked deflection. The currents used were very small. At present no exact ideas of their size can be given. Several sets of curves were obtained, showing the variations of E M.F. between ball and point, with small increments of time during a complete wave, both with and without the arc. They verified one another, and showed that as the point came to its highest positive potential the arc suddenly formed, and the potential difference between ball and point immediately dropped to a very low value, and remained there for about one-third of a complete wave, when the arc broke and the potential suddenly changed sign, jumping to its maximum value the other way. No arc forms from ball to point.

Zürich.—Ten firms have submitted tenders for the central station here, viz.:—Messrs. Crompton and Co., Chelmsford; J. Ehrenberg, Lucerne; Escher Wyss and Co., Zürich; the Uster Electrical Works; the Oerlikon Works; E. and P. Sée, Lille; Siemens and Halske, Berlin; Stirnemann and Weissenbach, of Zürich, representing Messrs. Ganz, Schuckert, and Sulzer; Thomson-Houston Company, Hamburg; and the Zürich Telephone Company. Six of the tenders were inadmissible because of their failure to comply with one or the other of the conditions originally laid down. The general programme laid down by the experts, says *Industries*, was based upon the employment of direct currents for the arc lights and alternating currents for the glow-lamps. The latter were to be fed by the least possible number of transformers, arranged in sub-stations, so that eventually, if reliable storage batteries should become available, the distribution of current to the glow-lamps could be on the direct-current system, in which case the alternators and transformers would have to be discarded. The project submitted by the Zürich Telephone Company, although the cheapest, was rejected because the arc lights were to be worked by alternating currents. Messrs. Siemens and Halske submitted two alternative schemes, one for alternating currents both for arc and glow-lights, and the other for direct currents on the five-wire system. The first was too expensive, and the second exceeded the limits of pressure fixed by the Commission. The project submitted by the representatives of Messrs. Ganz and Co. was based on parallel coupling of alternators; but the price was higher than that of the Oerlikon project, and the large number of small transformers distributed throughout the house was considered a serious drawback, not only for the present, but also because they made the future transition to the accumulator system more difficult. The Oerlikon project is based upon the use of direct currents for the arc lights, and alternating currents from large sub-station transformers for the glow-lamps. Each sub-station will contain one large and one small transformer, the first for the night and the latter for the day service. This arrangement has been adopted in order to minimise the loss of energy in magnetising the transformers when the demand for current is small. The Oerlikon tender has been accepted. The direct current dynamos will be of the Oerlikon type, and the alternators will be of the Kapp type.

THE PARIS EXHIBITION.

The Exhibit of the Thomson Electric Welding Company.

The Exhibit of the Thomson Electric Welding Company occupies a part of the same stand as the Thomson-Houston Company. Four separate welding plants are shown, each of a different type and size, the largest being capable of welding wrought-iron bars up to 2in. in diameter, or pipes of 2½in. Power for working them is supplied by an Armington-Sims engine of 80 horse-power, placed in the centre of the stand. The dynamos are of the alternating type, already described in connection with the Thomson-Houston exhibit (see *Electrician*, August 16, p. 373), and, with the exception of the "self-contained" plant, are worked in conjunction with transformers in the usual way.

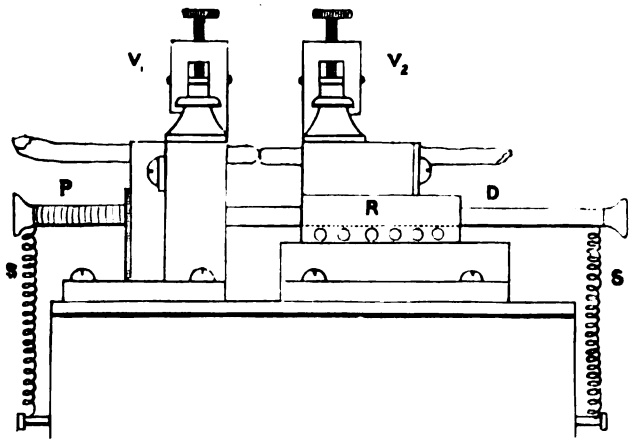

FIG. 1.—Thomson Automatic Electric Welder (Front View).

For the smallest work there is an automatic welder, provided with an arrangement by which the current is shut off when the weld is completed. Fig. 1 shows a front view, and Fig. 2 a side view of the apparatus. The clamps or vices V_1 and V_2, are mounted on a box containing the transformer, one of these, V_1, is fixed, the other, V_2, rests on small copper rollers, R, which allow free movement backwards and forwards, and at the same time keep good contact with the lower fixed portion; the vice V_2

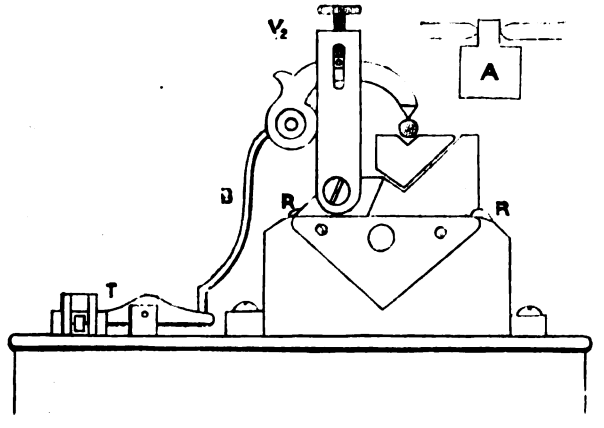

FIG. 2.—Thomson Automatic Electric Welder (Side View).

is held down by the springs S S, attached to the rod D, which passes through V_1 and is fixed to V_2. A small gauge, shown at A, Fig. 2, is slipped in between the clamps before the pieces of metal are made fast for the purpose of regulating the distance through which the sliding clamp travels before the current is turned off. The switch for effecting this is placed just behind the clamps (Fig. 2) and held back by a trigger, T, which is released by the pressure of a light adjustable arm, B, fixed to the moving clamp. When the two white hot ends of the pieces of metal to be joined have been sufficiently pressed together by the action of the spring P, the switch flies back and the primary circuit of the transformer is at once broken.

For regulating the strength of current supplied, Prof. Thomson has devised a "reactive" coil which is connected with the primary circuit in place of a resistance; it might be described as an adjustable "choking" coil. Its construction, which is quite simple, will be understood from Fig 3. A laminated iron ring, R, is fixed in a vertical position and wound over one-third of its circumference with wire P, which may be called the

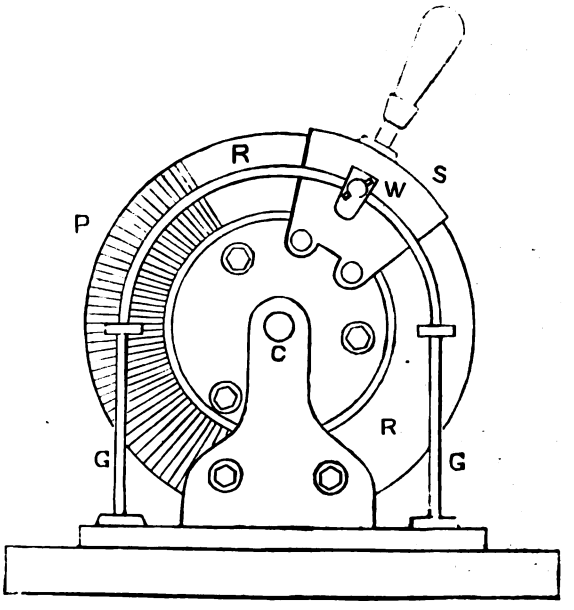

FIG. 3.—Reactive Coil.

primary coil, and through which the current from the dynamo passes. The centre is also filled with a laminated core moving on a spindle, C, and has a massive piece of copper S attached to it so as to surround the ring R. By means of the handle this can be turned over so as to envelop the coil P to any extent required, and its action is thus similar to a transformer with a movable secondary coil, the current in P increasing the more it is enclosed by the secondary S. By the aid of the clamping screw, W, and the guide rod G, it can, if necessary, be fixed in any position required.

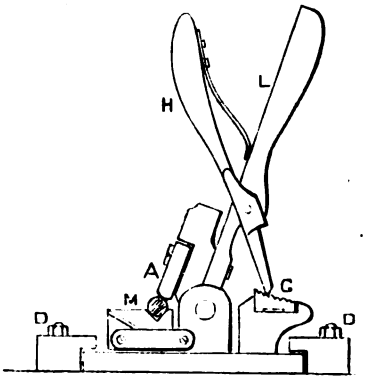

FIG. 4.—Electric Welding Clamp.

For welding iron up to ½in. in diameter a self-contained plant is exhibited. This is a most compact machine, and occupies a very small space. The bench for holding the clamps, switches, and adjustable resistance is supported above the dynamo itself by arms bolted on to the plummer block and pole-pieces. It is a two-pole machine of the motor type, with a drum armature wound with two sets of coils; one of them,

Digitized by Google

for exciting the field, is connected to a commutator at the end of the hollow spindle, and the other set, consisting of a number of single turns all joined in parallel, is joined up to rings or collectors, from which the current is led away at once to the clamps on the table above. The strength of the current is regulated by an adjustable resistance in circuit with the exciting coils. One clamp is fixed, as in the plant described above, but the other works between guides (D D Fig. 4), and is controlled by a lever for pressing one up to the other while welding.

An indirect plant of a different type is shown capable of welding iron bars up to 1in. in diameter. The clamps are mounted on a box containing the transformer, for which power is obtained from a 4-pole alternator similar to one of those already described in the Thomson-Houston exhibit. The machine is self-exciting, there being two sets of coils on the armature, and it gives 70 amperes at a potential difference of 300 volts. The power for the automatic welder is also supplied from this machine.

The form of clamp used in this and the preceding plant is shown in Fig. 4, and is specially designed to avoid the waste of time that takes place where the pieces of metal have to be screwed down in a vice. The piece of metal M is held down by the clamp A attached to the lever L. By gripping the two lever handles H and L, and at the same time drawing L forward, the lower part of H catches in the rack G and holds it fast. The whole slides between the guides D D, and is worked to and fro by a lever, not shown in the figure.

The welding plant for the heaviest work consists of an exciter, a 6-pole alternating machine of the type already described, giving 38,000 watts at a potential difference of 300 volts, and of the welder with its transformer. The core of the transformer, which is about 15in. long, is built up of rings in the usual way, and wound with a primary coil, making 17 turns and consisting of large stranded wires capable of carrying 130 amperes. The secondary coil, which has one turn only, is made up of a thick copper tube, 4½in. in diameter, passing through the centre of the core and bolted to a massive piece of copper at each end that has a sectional area of about 20 square inches. The vice, which is fixed and insulated, is attached to one of these blocks of copper, and the other vice is in connection with the second block, thereby completing the circuit through the tube and the bars to be welded. Before fixing the pieces of metal into the clamp it is found to be an improvement to file away the edges into a slightly conical shape which has the effect of preventing the bulging that usually occurs at the joint; this must also have the effect of slightly increasing the heat at the ends, since the sectional area is thus diminished.

I saw Prof. Thomson weld together in this large machine two pieces of 2in. round iron in the presence of the jury, and the time needed to complete the joint was surprisingly short. Practical demonstrations are given every day by Mr. A. S. Garfield, the welding expert of the company. This exhibit should do much towards bringing the process under the notice not only of mechanical engineers, but also of ornamental metal workers, since it not only renders it possible to effect a good joint where the old process is inconvenient, but, as is already known, in the case of some metals and alloys, where soldering and brazing are both found to be almost, if not quite, impossible. Numerous specimens of work are shown, including welds in chains, twist drills, spanners, &c., by no means the most uninteresting being the words *Soudure electrique*, made up of pieces of all kinds of metals joined together and arranged on a board above the stand.

REVIEWS.

Modern Views of Electricity. By Prof. Oliver J. Lodge, D.Sc., LL.D. F.R.S. (London: Macmillan and Co. 1889.)

(Continued from page 400.)

Amongst other subjects which come within the purview of the new ideas of electricity as set forth by Prof. Lodge are the magnetic properties of matter. Electricity in rotation *is* magnetism according to the new doctrine; and the magnetic forces are simply the tensions and pressures set up in the medium as the result of vortex motion. It might have been wished that Prof. Lodge had dwelt at greater length upon the quasi-rigidity possessed by bodies in motion, and had further developed his ideas respecting the structure of magnetic fields. His ingenious model mechanism to illustrate the ethereal medium is now required to perform a new duty. It must be adapted to illustrate how it is that when iron is placed in a magnetic field it affects and is affected by that field. How can the presence of iron increase the amount of rotation therein going on? How can the rotation going on in the field set the iron molecules, or rather the ether connected with the matter of those molecules, into rotation? Here, we must confess, the analogies become a little mixed, and perhaps a little forced also. Frankly accepting Ampère's hypothesis (in modern dress) that the molecules of iron (should it not be its atoms, rather?) have molecular currents circulating around them, it is laid down that these molecular currents are permanent in each particle, each atom being of infinite conductivity. [Atoms, in the modern view, have capacity and self-induction, but no resistance]. The act of magnetisation simply consists in making them all face round so as to be oriented in obedience to the magnetising force. So far so good. But when we have to account further for the permeability of iron, for its extraordinary power of multiplying the magnetic forces in the field, another and entirely new conception is introduced, having nothing to do with Ampère's hypothesis, namely, that the iron atoms are more dense than those of any other substance. The wheels, in fact, which represent in the model the atoms of iron, must be made heavier, so that though they are set rotating when the gearing rotates, there shall be a greator "amount" of rotation as the result; and, though it is not expressly so stated, it would appear that the intermediate negative wheels will require to be negatively dense in correspondence. Magnetic permeability is accordingly (pp. 206 and 222) defined to be density of the ether in or of the atom, a notion very difficult of acceptance. Consider the whole range of facts about magnetic permeability; how it is small, and constant, for all ordinary non-magnetic media; how it is large and variable for magnetic media; how in the case of iron it varies from 30,000 down to two or three, according to the stage of saturation; and how, lastly, at any given stage of saturation it may be quite different according as to whether the antecedent process was one of ascending or of descending magnetisation. Can all this be adequately represented by taking permeability as the density of the ether? How can the density of the ether in the iron vary, and the ether yet be incompressible? Even if the theory be possible, is it, after all, true or even probable? In face of the fact that the substances which themselves are magnetisable are also those which possess magnetic permeability, and that the two properties are probably only two aspects of the same phenomenon, is it not contrary to the rules of philosophising to attribute the one to the molecular currents of Ampère, and the other to the quite different cause of a hypothetical variation in the density of the ether?

If magnetisation and permeability are to require each such very different modes of explanation, how comes it that the permeability of iron at any stage is so nearly proportional to the difference between the actual value of the magnetic induction and the maximum value to which it can (practically) be pushed?

Prof. Lodge takes, indeed, his own special view of the Ampèrean currents. According to him they pre-exist, and the act of magnetisation consists (p. 149) "merely in facing them round, so as to look all one way." He supports this by the acute observation (which though at once obvious, we do not remember to have come across before) that the Ampèrean currents cannot possibly be originated by the act of magnetisation, as induced currents in the atoms, because (p. 154) they are in the wrong direction, and would (by Lenz's law) necessarily circulate in such a sense as to oppose the magnetising forces. He accepts Prof. Hughes's view—and we wish he had more fully discussed Hughes's experiments on molecular magnetism—that in an ordinary non-magnetised piece of iron the polarised molecules are shut up into little self-closed circuits, which open out when placed under a magnetising force. The ordinary "higgledy-piggledy arrangement" of the molecules is the arrangement of minimum energy to which all magnetised bodies tend to return; to which, indeed, all fluids, after having been subjected to a

Digitized by Google

magnetising force, instantly return. "Hence (p. 161) we learn that the specially demagnetising portion of a magnetic current (query current) is the fluid portion; and the greater the proportion of the fluid portion to the whole, the more easily is demagnetisation accomplished."

Nor is this the only serious criticism which must be made upon Prof. Lodge's new theory of the constitution of a magnetic field. Granting that a medium so constituted may act "in a very electrical manner," would it act in an entirely electrical manner? Even if it did, is not this construction of cogged wheels and slipping wheels, with alternate, positive, and negative rotations, too gross a caricature of the mechanism of the magnetic, or rather of the electromagnetic field, to be admissible? In the first place, the cogged-wheel diagrams absolutely refuse to work unless the wheels are arranged in square order. If arranged in any other, as are the cells in a honeycomb, as the columns in a basaltic rock, as spherical shot do when heaped up, as rings, or cylinders, or cones, or spheroids would do when heaped together, or in any other natural mode of aggregation, then they would absolutely refuse to work—the teeth of the gear would jamb. In the second place, though the diagrams represent as in one plane the wheel system, the author distinctly asks us to picture the medium as filled with such wheels, his flat pictures representing sections through vortex cylinders or vortex rings. This adds seriously to the difficulty mentioned above—that the wheel-work must necessarily be arranged in square order. Add to this the hypothesis that in electrolysis the positive and negative elements of the medium move pass one another in parallel processions (p. 86), and it will be seen that the complication becomes quite bewildering. Lastly, there is the serious objection that if cogged wheels devoid of slip are to represent a non-conducting medium, the very mechanical principle of cogged gearing intervenes to prevent the model from representing the facts; for if there be no peripheral slip no one wheel can rotate without every other wheel in the entire mass of the medium from end to end rotating through an equal angle, whereas the electrical facts require us (p. 188) to consider the rate of spin to diminish as the distance from the centre of disturbance increases. The model is, however (saving for the intermediate negative rotations), only an attempt to give the uninstructed a crude idea of vortex-motion, and those who have already studied hydrodynamics and know what vortex-motion is, will require no such model to fix their ideas. They will, however, thank Prof. Lodge for enabling them to see so clearly how it comes about that electric currents are propagated by lateral forces, not by end-thrusts in the wire, as the language of the ordinary electrician would lead them to suppose.

There is one other feature in Prof. Lodge's theory open, if not to criticism, at least to serious debate. By his views we are led back to a *two-fluid* constitution of the ether, whereas for the past quarter of a century we have been steadily progressing toward the other view that electricity whatever its ultimate nature was one entity, not two. The experimental reasons alleged for this retrograde step are enumerated on pp. 168-9, as six in number; but it is frankly admitted that several of these have nothing to do with the essential facts, and on p. 220 only three of them reappear. Let us examine these reasons for the alleged "doubleness of constitution." First, there is electrolysis; secondly, the absence of mechanical momentum in currents and magnets; thirdly, "the difficulty of otherwise conceiving a medium endowed with rigidity which is yet perfectly fluid to masses of matter moving through it." With respect to electrolysis, it is the most obvious fact that at the two opposite electrodes of the cell the two sets of atoms of the decomposed liquid are respectively liberated, and doubtless this looks very much as though there were two opposite currents, one positive, one negative. But there are two other facts, not quite so obvious, certainly not so universally known, which, however, are in such a matter quite as intrinsically significant, namely, that pure binary substances, such as pure water or pure hydrochloric acid, are not electrolysed, but require the presence of a third substance or of a solvent; and that in all electrolysis there is, over and above the decomposition of the decomposed substance, a motion of the substance *as a whole* through the liquid, so that it may be that the apparent travelling backwards of the electro-negative atoms may be nothing more than a result of the travelling forward of the rest of the binary substance. With respect to the apparent absence of mechanical inertia from electric currents, the search for an explanation of this, which crops up again and again in Prof. Lodge's book, seems to lead him almost a Will 'o-the-wisp dance. If electricity is not matter (and Prof. Lodge is apparently quite sure it is not), and if electromotive force is defined to be that which moves or tends to move electricity, why on earth should he expect electromotive force to move or tend to move matter? Prof. Lodge will probably live to smile at the importance he has attached to this idea of electric inertia. Lastly, with respect to the difficulty of conceiving otherwise of the requisite rigidity of the fluid medium, he surely must not omit the time question; for one has not to go any further than such ordinary fluids as air and water to see how such media, especially water, through which it is quite easy to propel solid bodies *slowly*, are enormously rigid (as the speed of sound through them shows) for rapid motions. Given such a further constitution as will make them for rapid motions rigid to shearing stresses, all the rest is a mere question of degree, and does not necessarily involve a duality of constitution. Time was when the ascent of a balloon would have been considered to conflict with the laws of gravitation. To explain it, apart from the properties of the air, would have required us to assume matter to be of two sorts, one of which obeyed a law of gravitation, and tended to fall, whilst the other obeyed a law of levitation and tended to rise. But no one now for a moment would seriously argue in favour of the duality of matter. We doubt whether the duality of the ether is true; we dispute the necessity of such a hypothesis to explain the facts of electricity. Prof. Lodge objects to the plain statement that the ether is electricity; in lieu of this he prefers to say that "the ether may be sheared by electromotive forces into positive and negative electricity." This may be something more than a play upon words; but if so, what is the meaning of the "neutral ether" mentioned on p. 350? Is it the same thing as the "neutral electr city" of the two-fluid electricians which can be decomposed into positive and negative?

The fourth part of Prof. Lodge's work relates to electric radiation, and here he is on his own peculiar ground. Having pointed out how the discharge of a Leyden jar is oscillatory, and how it sends out waves into the surrounding medium, he shows how to calculate from the static and magnetic capacities of the circuit the frequency of the oscillations, and the length of the resulting waves. He works up the subject toward the electro-magnetic theory of light in the following ingenious way:—For a condenser having a capacity of 1 microfarad, discharging through a circuit of 1 secohm inductance the rate of oscillation is 157 per second, and the wave length about 1,200 miles. For a common pint jar discharged through a pair of tongs will set up waves not longer than 15 or 20 metres, at the rate of ten million per second. For a thimble-sized jar the waves may be only about 2 or 3 feet long. "Continue the process of reduction in size further, and ask what sized circuit will give waves 6,000 tenth-metres (or 25 millionths of an inch) long. . . . This gives us at once something near atomic dimensions for the circuit, and suggests immediately that those short ethereal waves which are able to affect the retina, and which we are accustomed to call 'light,' may be really excited by electrical oscillations or surgings in circuits of atomic dimensions." So much of the volume is devoted to the development of the relation between optics and electricity that it is impossible to discuss this section in the necessarily limited space of a review. A fair account is given of Kerr's researches, but the explanation offered by the author of the rotation of the plane of polarisation, according to which it depends upon hysteresis, is open to serious doubt. It conflicts further with Kundt's classification of substances according to their properties in this respect.

There are many good things in the book which have not yet been noticed: the capital comparison between heat-conduction and electrical conduction on p. 66, the contrast between an electric telegraph and the oft-attempted magnetic telegraph on p. 198, the judicial pronouncement on the volta-contact theory on p. 109, the hitherto unpublished researches on pp. 11, 121, 154, 160 and 215, and the acute observation on the dissipa-

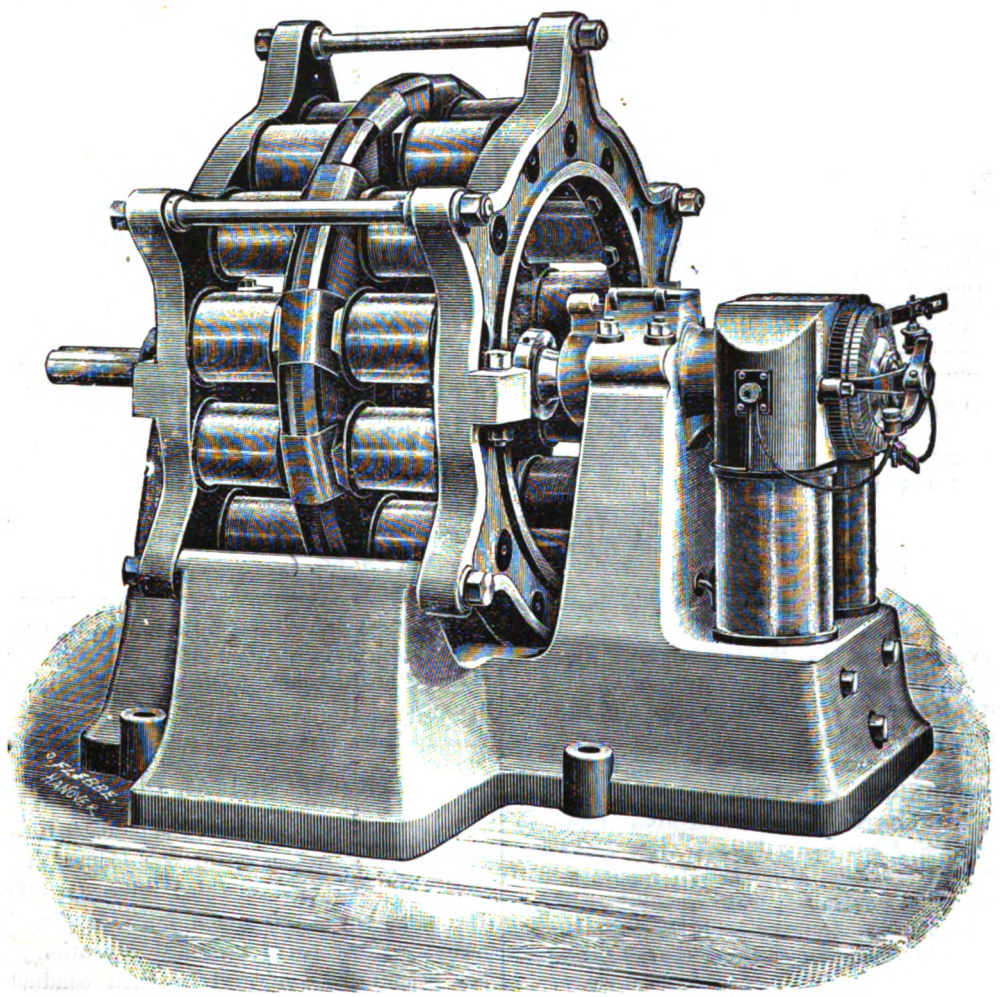
Digitized by Google

tion of energy by substances of intermediate conductivity on p. 274.

There are also some weak points of a minor order. The term "throttle" is used on p. 243 in a sense different from that introduced by Lord Rayleigh. Young students and general readers will be puzzled by the use of the words "speed" on p. 69, and "path" on p. 161, the sense of which is not defined. No mention is made of Warburg's researches on work lost in a cycle of magnetisation, which preceded those of Ewing. But these are minor matters and can readily be adjusted when a second edition is called for. Prof. Lodge's book is certainly successful in its main attempt to bring vividly forward in a tangible and non-mathematical manner the gist of modern knowledge respecting the real nature of electrical actions and of electricity itself. No one can rise from even a first reading of Prof. Lodge's book without feeling that he has made a big stride toward understanding what electricity itself is. But this is not saying that everyone will find the book easy reading. It is not by any means all milk for babes. But then Prof. Lodge is a strong man, and writes for strong men.

THE KAPP ALTERNATOR.*

Schio, a small town in Northern Italy, has now a central electric light station, which has been erected to the order of a local company by the Oerlikon Engineering Works. The generating and transforming plant is of the Kapp type, made by the Oerlikon firm, and the accompanying illustration, for which we are indebted to our esteemed contemporary, *Industries*, represents one of the two alternators at this station. In this machine the armature has an iron core, composed of thin band iron coiled upon a cast iron supporting ring, and provided with fibre driving horns, by which the armature coils are supported. The field-magnet cores are cylindrical, and of wrought iron 4⅛in. diameter, secured at their outer ends in cast-iron yoke rings, and provided at their inner ends with rectangular pole shoes, between which the armature revolves. On the armature there are 14 coils, each consisting of 80 turns of 120 millimetre wire wound in two layers, and the armature resistance is 1·8 ohm. There are 28 magnets, each wound with 186 turns of wire, and the total field resistance with all the magnet coils in series is 1·76 ohm. The machine, when driven at 600 revolutions per minute, is intended for an output of 30 amperes at 2,000 volts terminal pressure; but, on trial, has been loaded up to 40 amperes. As will be seen from the illustration, an exciting dynamo is combined with the alternator, the magnets of the exciter being fitted into a prolongation of the main bed-plate, whilst the armature is mounted on the spindle of the alternator. This dynamo is used not only for exciting the field of the alternator, but also for lighting the station. The following figures, supplied by Mr. C. E. L. Brown, of the Oerlikon Works, give the result of a test of the machine. The speed was, during the test, kept constant at 600 revolutions per minute, and the terminal pressure was noted for different degrees of excitation, no current being allowed to flow through the armature of the alternator:—



Kapp 60-Kilowatt Alternator

Exciting current amperes.	Exciting energy. Watts.	Terminal pressure. Volts.
9	142	1,000
14·5	368	1,700
17	510	2,000
18	573	2,100
21	775	2,400

When a current of 30 amperes was allowed to pass through the armature, the terminal pressure of 2,000 volts was obtained with an exciting current of 21 amperes. This requires an expenditure of energy for excitation of 775 watts, or about 1·3 per cent. of the total output; whilst the loss in the armature due to its resistance is 2·7 per cent.

*. From *Industries*.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

THE TECHNICAL INSTRUCTION BILL.

In spite of the determined opposition with which it has been met by a certain portion of the House, the Technical Instruction Bill was read a third time on Wednesday evening. We have never put much faith in the sincerity of Parliamentary advocates of technical education; and our suspicion has been fully confirmed by their conduct in the House of Commons during the present week. Had there been any strong and general desire to pass the Government Bill dealing with this important subject, the insignificant band of obstructionists who have kept the House into the small hours of the morning wrangling over petty amendments, which had no other object than to delay and defeat the measure, would have been met by a larger and more determined body than the fifty or sixty Government supporters who languidly followed it into the division lobby. As to the 15 or 18 malcontents who occupied themselves in concocting fresh reasons for reporting progress, or discovering grave defects in the Bill, it has been plain from the first that they had made this a sectarian struggle, and that to secure a sort of negative triumph for the Board Schools was deemed of far greater moment than to make any positive advance in technical education. That the Board Schools would not be entrusted with the task had become evident in the earlier part of the Session; and

Digitized by Google

from that time to this there has been a dogged determination on the part of the Board School partisans to prevent anybody else undertaking it. On the other hand, the friends of Voluntary Schools are by no means anxious to figure as opponents of Board Schools; and their desire to see technical education placed outside the influence of one set of schools is not proof against their latent desire to see both sets controlling it equally.

The history of the Bill has been rather singular, and is highly instructive. Last year it escaped any direct opposition, partly because of the prevailing enthusiasm for technical education, which was then thought to be the only possible safeguard against industrial ruin; and the Bill was only suffered to lapse through there being no time to pass it. This year, with renewed signs of prosperity, the enthusiasm seems to have cooled down; but, at all events, on its reintroduction in the present Session the measure was met by a criticism which speedily put an end to its career. The Technical Education Bill was withdrawn by the Minister who had charge of it, with the frank declaration that it was beyond the ingenuity of man to frame a measure of that kind to satisfy the conflicting aims of Board School and Voluntary School partisans. Sir W. Hart-Dyke, however, had underrated his resources; for, after a few weeks' reflection, he had contrived a Bill which avoided all the snares of its predecessor, and which might reasonably be expected to disarm the hostility of Board Schools and Voluntary Schools alike. This was a Technical Instruction Bill, the essential change in its character being indicated by the fact that the system proposed was not to form part of the national education of the country, but to be administered by the Technical Department of South Kensington, and supported out of the rates levied by local authorities *other than* Board Schools.

This was an ingenious device to conciliate the friends of Voluntary Schools, to whose interposition the failure of the Technical Education Bill was due. They had urged, and we think with justice, that to give the Board Schools the exclusive right to raise money for technical education, as the original Bill proposed to do, would be not only unfair to Voluntary Schools, but unsatisfactory to the country at large, seeing that a very large proportion of the industrial classes are still educated in schools supported by voluntary contributions. So obvious was this contention that no sooner was it put forward than the fate of the Bill was sealed. It would have put technical education exclusively in the hands of rate-supported schools, and would have exposed the Government to the charge of compelling Voluntary School pupils to attend Board Schools in order to obtain the sort of training which Parliament had declared to be desirable for all classes of pupils. Much to the discomfiture of Board School representatives, however, the Government, as we have said, discovered a way out of the difficulty, affording technical education, supported from non-sectarian sources, for all who cared to avail themselves of it. The Bill had the twofold merit of separating the combatants, and allowing technical education to be perfectly voluntary. But one of the combatants was determined not to be kept back. Board Schools are the recognised educational machinery, and to none but Board Schools should the right to tax for educational purposes be transferred. Such was the attitude taken up by the partisans of the Board School system; and it meant nothing less than this, that if the Board Schools were not allowed to continue in their exclusive right, there should be no rate-aided technical education at all.

Although the Bill has assumed its present shape, so to speak, by accident, and only as a working compromise, it seems to us to be a measure which is eminently practical and to the point. There is a distinct advantage in handing over the business of technical instruction to a technical department; and although South Kensington is not all that could be desired, it is much to be preferred to the Schools Boards, who would each work independently and on no consistent plan. The local authority responsible for raising the funds may be trusted to supply them only where the requirements of the town or district demand such help. Managers of Board Schools, on the other hand, as we know by past experience, are only too anxious to add to the list of subjects taught anything that will increase the importance of the management. Indiscriminate technical instruction, irrespective of the needs of the pupils, would be worse than useless, being thrown away on lads who do not want it, and not carried far enough for lads who do want it. The voluntary technical classes which it is intended to encourage under the present Bill are just what is needed to test the question whether the rising generation artisans desire to be technically instructed, and to determine the precise kind of instruction most needed in the several localities.

PARIS INTERNATIONAL ELECTRICAL CONGRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

Friday, August 23.

Although the official opening of the Electrical Congress took place on Saturday, the proceedings may be said to have really begun on Friday evening last, when a joint meeting of the Institution of Electrical Engineers and the Société Internationale des Électriciens was held at the Société d'Encouragement. Sir William Thomson was voted into the chair. Colonel Sébert was the first speaker. He spoke a few words only, offering in a very pleasant and cordial manner a hearty welcome to the company on behalf of the French Electrical Engineers. Sir William Thomson next spoke and gave a short *résumé* of the history of electrical progress since 1881, the date of the last Congress Sir William began his speech in French, and was proceeding apparently quite to the satisfaction of his French audience when he suddenly resumed the use of his native English, declaring, much to the amusement of his hearers, that he would try their patience no longer by his halting attempts to speak the language of the place. M. E. Mascart followed with a speech, in which he complimented Sir William individually and everybody else generally, and thus succeeded in producing good humour all round. After this M. Chardonnet entered into an explanation of his newly-invented process for the artificial production of silk, which he illustrated by a small working model, the fact that the model was worked by an electric motor being apparently considered a sufficient justification for the introduction of the subject at an electrical congress. Decidedly the most interesting feature of the evening came next, in the exhibition by M. Carpentier of his "Mélographe." This is an electric arrangement whereby a piano which is played upon, prints or marks the music on paper in such a manner that the same music may be reproduced mechanically by passing the marked or printed paper once more through the piano. In principle this instrument is not new, but M. Carpentier has brought the mechanism and the general design to a high degree of perfection. At present we understand he has no idea of making his invention useful to musical composers, but we see no reason why it should not be developed into a convenient system whereby composers may delegate to assistants the drudgery of producing their copy in proper form for the printer. This instrument is to be on exhibition during the whole of the Congress week. An exhibition of the Edison phonograph was then given by Col. Gouraud, and a buffet supper, at which Mr. Edison assisted, brought the meeting to a close. Amongst the various exhibits of the evening was a specimen of a Crompton armature winding, and a very convenient form of potentiometer, also devised by Mr. Crompton, who himself explained the instrument to Mr. Edison, Prof. Hughes, MM. Potier, Hospitalier, and others. The potentiometer has a four-metre bridge with multiple switch, so that six separate E.M.F.'s can be compared with a standard cell.

Saturday, August 24.

On Saturday morning, at 10 o'clock, the Conference was formally opened by a speech by M. Mascart, in which he explained the arrangements made for the succeeding week, and by the election of office-bearers. M. Mascart having been elected president on the motion of Sir William Thomson, M. Fontaine proposed, and it was resolved, to appoint Sir William Thomson Honorary President, and MM. Cochery and Berger "Presidents d'Honneur." There were further chosen six Vice-Presidents, namely, MM. Ferraris (Italy), Kareis (Austria), Potier (France), Preece (England), Rousseau (Belgium), Stoletow (Russia), and Weber (Switzerland). M. Joubert, Secretary of the French Physical Society, was appointed Secretary. The "Comité d'Organisation" had proposed to form six sections of the Congress, but it was formally resolved to reduce the number of sections to four. Thus the originally proposed second, third, and fourth sections (which were devoted respectively to machines, electrochemistry, and lighting) are now combined in one, the second. This simplification is felt to be a great improvement, as the same people practically desire to attend the meeting of all the three original sections now amalgamated. It is estimated that about 800 persons attended this opening meeting, but not more than a hundred entered their names on the register, and of these only a very small number put down their Paris addresses.

On Saturday evening a demonstration of "Electric Undulations" was given by M. Egoroff, at 44, Rue de Rennes. These very beautiful experiments have aready been described by J. J. Thomson, in England, before the Royal Society. They consist in an extension in a particular direction of the researches of Hertz. M. Egoroff's apparatus worked very perfectly on Saturday last, but M. Egoroff himself, who is a Russian, has not the faculty of clear public exposition, and, in fact, he addressed a large portion of his remarks in a low conversational tone to the wall instead of to his audience. The vacuum tubes he uses, and in which the phosphorescent arc light is produced, showing the passage of electric energy through the air in which they are placed, are ordinary Geissler tubes, prepared by the ammoniacal process. Only certain tubes, however, exhibit the phenomenon, and M. Egoroff cannot as yet distinguish beforehand which tubes will and which will not do so. He is clear, however, as to the behaviour of the tube depending in some respects upon its exact dimensions. M. Egoroff uses an alternating current, and two or four brass or copper plates, between which the electric energy is radiated or discharged through the dielectric medium. The plates were on Saturday placed parallel in the same plane. In the space close to the plates the vacuum tubes exhibit a vigorous glow, the production of the light, however, depending on the position in which the tubes are held with regard to the lines along which the electric energy flows, these lines close to the conductor having been shown by Prof. Poynting to be normal to the surface of the conductor. Also, the tubes can be shaded from the action by the interposition of many substances, such as rubber silk or cardboard. Parallel conducting wires being stretched from the centres of the plates to the other end of the room, the passage of energy through the space between and around the wires is manifested by help of a large insulated ring of copper wire, the circuit of which ring is broken at one point so that the alternating current generated in it is exhibited by sparking between the points of the break. As this apparatus is varied in position along the wires so as to place it at different distances from the charged plates, the light waxes and wanes, thus showing the nodes of the interfering waves of electrical excitation in the dielectric. M. Egoroff made a main point of insisting on the circumstance that the places of maximum electrical excitation were also places of maximum magnetic strain; but it must be confessed that his experiments to prove this seemed to give very indefinite visible results. This *séance* was attended by over a hundred members.

Sunday, August 25.

On Sunday morning, at the early hour of eight, a large company of Congress men, with a few ladies, assembled at the base of the Eiffel Tower, and proceeded, under M. Mascart's escort, to inspect it. Although there is nothing to see at the top beyond an ordinary electric lighthouse arrangement and ordinary meteorological instruments, those who got there insisted on examining these in so leisurely a manner that M. Mascart at last declared that he had made a calculation that it would take seven days to get the whole company through if the circulation continued at that rate. He therefore peremptorily declared that the ascent should stop, and enforced this declaration by causing a ladder to be dismounted from its bearings and an iron trap door to be lowered on the heads of the unfortunates below. At one time it was feared that the friction between the up and down streams on the staircase had caused a charge of dangerously high potential to accumulate on the outer surface of the Tower, but this was ascertained to be an unfounded rumour, probably because of the dissipating action of the large number of lightning conductors sticking out from all points of the structure. Happily no serious misadventure took place, and an hour later the *élite* of the scientific world became dispersed and lost in the vulgar crowd of humanity on the lower stages of the Eiffel Tower and in the gardens below.

Monday, August 26.

On Monday morning the Sections met at nine o'clock, and with very little delay proceeded to business by completing the appointing of officers. From the extremely short time in which this was accomplished it was apparent that everything had been settled beforehand so far as this part of the proceedings was concerned. If the same forwardness of preparation had been evidenced as regards the papers, the time of the first day might have been utilised to a greater extent. The following is a list of the official appointments:—

Section I.—Units and Measures: President, M. Lippmann; Vice-Presidents, MM. Bjerknes and Stoletow; Secretary, M. Violle; Assistant-Secretaries, MM. Armagnat and Lepage.

Section II.—Industrial Applications: President, M. A. Potier; Vice-Presidents, MM. Ferraris, Hippolyte Fontaine, G. Forbes; Secretary, M. E. Hospitalier; Assistant Secretaries, MM. C. Jacquin, J. Laffargue, G. Roux.

Section III.—Telegraphy, Telephony, and Signalling: President, M. Fribourg; Assistant Secretary: M. Dumont.

Section IV.—Electro-Physiology: President, M. Gariel. Assistant Secretary, M. P. Bary.

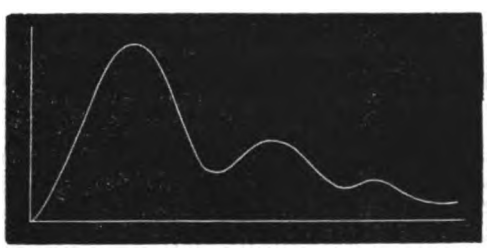
This preliminary business over, M. Crova proceeded in Section II. (Industrial Applications) to read a Paper whose object was to suggest improved and more systematic methods of comparing lamps with respect to their lighting power; in other words, it advocated the introduction of methods of photometry founded on more rational principles. He asked that the definition of the lamp should include three things—first, the voltage for its normal intensity; second, the tint or colour composition of its light; and third, its lighting power. By the help of curves of intensity, the horizontal ordinates being reciprocals of the wave lengths or of the period of vibration, each lamp having a curve peculiar to itself, a comparison with sunlight was established in very much the way as has been so very frequently done by others. Where the curve of a lamp crosses the sunlight curve the same intensity is obtained from both sources. A number of figures were given regarding the watts at various intensities, and the watts at the "point of extinction," *i.e.*, the point below which the lamp is not incandescent. Measurements of the intensity in the various horizontal directions from the lamp were compared by means of polar curves, and it was proposed to try to get a mean of these by revolving the lamp at a suitable speed on the photometer, but either from actual variation in the light or from imperfection in the arrangement of the apparatus, there appeared to be practical difficulty in getting a satisfactory mean. The colour compositions were taken by means of a comparison of the values of the red in each light at a wave length of 557. In each lamp the tint thus determined varies largely with the number of watts. The discussion following this Paper was limited to a few remarks addressed in a very informal way by the chairman to the reader of the Paper, and a spirited attack upon the whole principle of the Paper by M. R. V. Picou, who said that under the various conditions of actual practice the power most economically spent upon a lamp depends upon the cost of mechanical horse-power in each particular locality and is extremely variable, and

Digitized by Google

that, therefore, there was no "normal" intensity or number of watts which could be said to be proper to each lamp. M. Crova's Paper, however, was generally admitted to be a very methodic and scientific attempt to introduce greater rationality into the photometry of electric lighting.

The president, M. Potier, now announced, considerably to the surprise of most people, that this was the only Paper that was offered for the first day, whereupon M. Bède charitably offered to assist the Congress on its way by giving an impromptu explanation of his views upon the combination of the heating with the electric lighting of industrial and other establishments. These resolved themselves pretty much into a recommendation to use for the heating the exhaust steam of the engines needed to drive the dynamos, running the engines throughout the day by charging accumulators with them, which accumulators would assist the dynamos during the dark hours. Thus the dynamo plant, including its driving engine, was reduced in size and cost, and the cost of separate heating boilers was avoided. This, of course, is a most serious and important industrial question, but its logical necessary connection with electric lighting seems doubtful, seeing that the exhaust steam from an engine can be equally well utilised for heating whatever description of work the engine may be doing, whether driving a dynamo or any other kind of machine. At any rate, the section did not choose to discuss it, and, after an hour and a-half of intellectual labour, suspended its meeting.

Meantime Section III. had been listening to an excellent Paper, by M. Mercadier, upon the relation between the intensity of sound emitted from a telephone receiver and the thickness of the vibrating diaphragm, the results of his experiments, as illustrated by curves which have the same characteristics as diffractional curves. The general character of the curve obtained is shown in the subjoined sketch, where the horizontal



ordinate gives the thickness of the plate, and the vertical the intensity of the sound emitted by it. It will be seen that this intensity at first increases with the thickness, then decreases, once more increases to a maximum, then, after falling to a lower minimum than the first, increases to a third maximum. His method of determining the intensity of sound consisted in determining exactly the distance at which it ceased to be heard. Unfortunately his arrangement gave this distance in a way that evidently depended on the sensitiveness of the ear of the experimenter, and as this would vary from day to day and also from hour to hour even if the measurements were all made by the same person, the results were felt to be to some extent vitiated by this circumstance. Thus with very thin diaphragms great intensity can be obtained, but the power of articulating—the power of reproducing all the minute distinctions of sound upon which speech depends, increases rapidly with the thickness. Therefore a middle course has to be followed by adopting a plate of such thickness as will give sufficient intensity, and at the same time a high degree of articulation. The harmonics of the plate alone were insufficient for such articulation, and the theory adopted by M. Mercadier is that besides the molar vibrations of the plate taken as a whole, there arise "molecular" vibrations capable of originating sonorous waves in the surrounding air. *How* such vibrations could be produced by merely internal molecular motions was not explained, and this theory is repudiated by Messrs. Hughes and Preece, the latter of whom, speaking in English, announced in this Section, on the following morning, their adherence to the more ordinarily understood theory of molar vibration of the plate. In this Section also, there proved to have been only one Paper provided for the first day, and the discussion of it was not even commenced before the adjournment.

In Section I. (Units and Measures) the first communication was from M. Bjerknes, who gave a *résumé* of his most recent researches into the analogies between hydro-dynamics and electro-dynamics. The President laid before the Congress the proposition of M. Pellat to adopt an electro-dynamometer-balance as the standard instrument for the measurement of currents. This brought forth a protest from Sir William Thomson, who said that with proper precautions the electrolytic method was far the most accurate, and that his own electro dynamic-balances were all calibrated by help of a voltameter. He said that there was no difficulty in getting accuracy by this system from 0·01 to 500 amperes. M. Mascart and M. Lippmann both agreed with Sir W. Thomson, and thus M. Pellat's proposal was at once crushed out of existence.

The question of measures of potential was introduced by Sir W. Thomson, who insisted on electrostatic methods, and said that nowadays an electrometer to measure 5,000 volts was an easy thing to make. M. Lippmann then explained capillary instruments for measuring small potentials, and declared that these instruments can be made to show $\frac{1}{10000}$ of a volt.

Section IV. (Physiological) found little to do. The President read a Paper by M. Maurice Mendelssohn on "Some Electrical Phenomena in Man," and then the meeting was adjourned until Friday.

In the afternoon the members made visits to the Telegraphic and Telephonic Sections of the Exhibition. Here M. Mercadier expounded his various exhibits, and a long series of Hughes's instruments of rather ancient pattern attracted attention. Mercadier's acoustic multiplex telegraph excited much curiosity, but Baudot's and Munier's quadruplex instruments contributed the greatest novelty and interest to the visit. Munier's arrangement is the more complicated of the two so far as mechanical arrangement is concerned, but Prof. Hughes seemed to feel a prefereuce for it on account of its greater magnetic simplicity. The four instruments combined can transmit along the one wire 650 letters, or about 140 words per minute, each instrument making 35 turns per minute, and averaging one word per turn. After leaving the Pavilion of Posts and Telegraphs most of the members made their way (*viâ* the Decanville Railway) to the pavilion of the Société Générale des Telephones, which lies just to the east of the Eiffel Tower. Here is the Telephone Exchange connecting the numerous subscribers within the Exhibition, and the general Parisian system.* This pavilion also contains an extensive collection of telephonic apparatus, including batteries, switches, call-bells, and cables, but there is nothing calling for special comment. In a room on the ground floor the members had the privilege of listening by telephone to a morning performance then proceeding at the Folies Dramatiques. With this episode the conjoint labours of the day were brought to a close.

Tuesday, August 27.

On Tuesday morning the Sections met as usual at nine o'clock. In Section I. the first Paper was from Mr. Van Aubel, who recommended for the measurement of the intensity of magnetic fields the methods of Profs. Stenger and Angström as being by far the most accurate. The bismuth spirals of Lenard and Howard are good for workshop measurements, especially when the fields are intense and of small volume; but as the resistance changes with the intensity of the field according to an unknown law, a calibration of each spiral is needed. An interesting and lively discussion then arose on the subject of nomenclature, introduced by M. Szarvady, who pointed out that the Congress of 1881 had omitted to establish any practical unit of magnetic intensity, and endeavoured to supply the omission. His definition of the unit was that intensity of field which would produce one volt electromotive force in a conductor one centimetre long, when cutting nominally the lines of the field at a velocity of kine (1 centimetre per second). This unit would be 10^8 C.-G.-S. units, but a more convenient size of unit for practical purposes would be 10^7 C.-G.-S. units. The name "Gauss" was proposed for this unit. M. Guillaume then advocated the adoption of the megadyne per square centimetre, with the name "barie"

* For an outline description of the methods adopted in the Paris Exchange, see *The Electrician*, May 31, 1889, p. 86.

Digitized by Google

as the unit intensity of mechanical pressure, apparently in ignorance of the adoption in England last year of the term "barad" to mean 1 degree per square centimetre. A unit of entropy was proposed by M. Moser, who wishes to call it "trop," for apparently no particular reason except that there are four letters in the word, and that these four enter into the word entropy. The definition of the "trop" was

$$1 \text{ trop} = \frac{1 \text{ joule}}{1 \text{ degree c.}}.$$

On the proposition of Mr. Violle the $\frac{1}{20}$th part of the absolute photometric unit proposed by the 1884 Conference was adopted as the "bougie decimale," it being very nearly $\frac{1}{10}$th of a carcel. A number of names having been proposed and carried to add to the committee to report on units, the meeting ended after a description of a bi-polar induction apparatus, whereby the elliptic motions of planets and their simultaneous rotations on their own axes could be reproduced on a small scale.

In Section II. the Committee appointed the day before reported their recommendation that incandescent lamps should be judged according to the following definition:—"The degree of incandescence of a lamp is the quotient of the intensities (relatively to the carcel) of its two radiations of wave-lengths $\lambda = 582$ and $\lambda = 657$." They also recommended that the "statement of the lighting power of a lamp should be accompanied by the statement of the degree of its incandescence at that power," and that "this lighting power should be stated in 'bougies decimales.'" The Congress confirmed these recommendations by vote. The subject of photometry was discussed further for some time. Prof. Silvanus Thompson then read a mathematical Paper on continuous-current transformers, and referred to an installation at Ipswich, where the transformer reduced the voltage from 1,500 to 100. M. Maurice Leblanc then explained how he had succeeded in reducing the effects of self-induction in alternating-current motors (see *The Electrician*, August 2, *et seq.*). Mr. Gisbert Kapp protested against this gentleman's low estimate of the character of existing alternating-current dynamos, and cited the experiments by Mr. Mordey.

The proceedings in Section III. began with Mr. Preece's statement on Mr. Hughes's and his own behalf already mentioned. M. Merczyng then described a new long-distance telephone arrangement, the line having a resistance of 2,000 ohms and a capacity of three microfarads. The specialty consists in separating the line from the transmitter and the receiver by two condensers, of which that at the receiving end is always to be made of smaller capacity than the other, the two actual capacities being 0·2 and 0·5. The line is an iron wire 300 kilometres long and five millimetres in diameter. Then followed a long discussion on the use of dynamos in telegraphy, introduced by a Paper by M. Pierre Picard. He gave a short historical review of this subject, referring specially to Schweindler's attempt to make the differences of potential on the various lines proportional to their resistances by their interpolation of suitable extra resistances on the short lines—the want of economy in which system was strikingly illustrated by the extra resistances being often greater than the whole useful resistance—and to the New York installation, where three series of five dynamos each are used, giving each 75 volts, and where four of each set of five can be arranged in series so as to give 300 volts. The author then described his own system, which has been in operation in Paris over a year. It consists in taking what may be called the main current (15 to 20 amperes) through a resistance of from 5 to 6 ohms. This resistance is carefully graduated, and forms a scale of potentials from which the various currents are taken off as shunts at different suitable points. M. d'Infreville informed the Congress that this system has been used in America by the Western Union Telegraph Company for the last eight years, both Siemens and Edison-Hopkinson dynamos being used. It is also used for the "Gold and Stock Telegraph." It was stated that great economy has resulted from the use of the dynamos. Mr. Aylmer explained the progress made in this direction by the British Post Office, Mr. Preece's first efforts dating from 1873, and the system being now, as is well known, modified by the introduction of a battery of accumulators charged once a month by the electric-lighting dynamos. He has now 220 circuits served by 29 accumulators. The rest of the sitting was occupied by a description of the new telephonic post of M. Van Rysselberghe and a discussion on the construction of cells of constant voltage.

In the afternoon, the Sections, in three separate parties, made visits to the works of the Société Générale des Telephones, the Laboratoire Central d'Electricité, and the works of Sautter et Lemonnier. The installation at the Laboratory comprises a semi-fixed horizontal 20 horse-power Weyher and Richmond engine, and a 12 horse-power Lenoir gas-engine. The machine room contains a Sautter-Lemonnier dynamo, giving 70 volts and 300 amperes; an Edison machine giving 10 volts and 80 amperes; a self-excited alternate-current Gramme machine, distributing boards and rheostats. The large photometer room contains a Bunsen photometer with Dumas balance, and a Mascart photometer; the laboratory standard of light being the carcel burning 42 grammes of oil per hour. In the electro-chemistry room there is a battery of 200 Callaud cells and a battery of 60 Julien accumulators. The standardising room contains instruments of great precision for standardising resistance, E.M.F.'s, and intensities, and comprises Wheatstone bridges, a Pellat electro-dynamometer, standard ammeters, standard voltmeters, and a Mascart electrometer. The standard resistances are five glass and mercury copies of the principal standards of the Ministère des Postes et Télégraphss. In the two rooms for commercial measurements, there are two Thomson and three D'Arsonval galvanometers, a Carpentier dead-beat electrometer, a Lippmann electrometer, two Wheatstone bridges, two graduated condensers, and a collection of rheostats and various other apparatus. In addition to these rooms there is a large one for carrying on any tests that may be required, and there at the present moment Hertz's experiments are being constantly reproduced under the direction of M. Joubert. The visit to the Sautter et Lemonnier Works was most interesting. M. Lemonnier himself was guide to the company, and it was difficult to know which to admire more, the immense practical energy of the man or his clear-headed, distinct, and succinct descriptions of his machines, &c. In the midst of the noise and distraction of the workshop his little speeches at each halt would compare very favourably in point of *netteté* of expression and clearness of tone with most of the often rambling and incoherent discourses we have been listening to in the Sections of the Congress. The chief objects of interest to which attention was drawn were dynamos driven by, and mounted on the same shaft as, a form of Parson's steam turbine, giving a double grade of expansion to the steam. The normal speed is 7,000 revolutions, at which the external electrical output is 85 volts and 100 amperes. The consumption of steam is very high, being 40 kilogrammes of steam at 5 atmospheres pressure per external electrical horse-power. But evidently the extreme simplicity and very great compactness of the arrangement may in very many situations, and especially on ship-board, compensate amply for the high rate of steam consumption. A military search-light, with automatic regulation added to the hand manipulation, which latter gives the greater possibility of nice adjustment to maximum lighting power, was examined; and then a photometer for arc and incandescent lamps, whose principal interest lay in its having been designed and constructed many years ago, and yet containing some of the arrangements just now being advocated at the Congress as improvements. The visitors next examined the manufacture of the carbons for the arc lamps. These are all of the plain cylindrical form, running up to 2½in. diameter, and the carbon being mixed with petroleum. This pleasant and interesting visit concluded with an afternoon luncheon.

In the evening there was a brilliant company of *savants* gathered at the invitation of Mr. Preece and Mr. James Dredge, in honour of Mr. and Mrs. Edison at the Pavilion of the British Section of the Exhibition. Here the attractions were chiefly social, but there were on exhibit a number of Edison Telephones in connection with the Opera House, and Phonographs, two of which were giving off instrumental symphonies that had been played into them some weeks ago, and the third was engaged in reproducing whatever anyone liked to speak into it. These instruments were all acting in a wonderfully perfect manner.

The following is one of the Reports which have been presented to the Congress :—

Electro-Physiology.

REPORT BY M. D'ARSONVAL.

The part played in therapeutics by physical agents (heat, electricity, pressure, cold, &c.) becomes more important each day, and that rightly so. The employment of physical agents is not complicated with any poisonous effect ; their action can be easily regulated and the application repeated without the least inconvenience. Modern physiology has proved that electricity, of all the physical excitants, is the most simple and efficacious for stimulating the functions of the nerves and muscles ; and furthermore the recent progress of electrical science has shown that we possess no agent which can be more easily managed than electricity. A great number of practitioners to-day employ electricity with success, but in order that their observations may be of any value for the advancement of science, and that the facts which they put forward may be checked, it is most necessary that they should know how to state precisely the conditions under which they worked. To attain this end, doctors employing electricity must learn to use the precise and simple language of electricians, and when they take the trouble to make measurements must give up using arbitrary ones. The Congress of 1881 has already made great progress in rendering obligatory in therapeutics the employment of the volt and milliampere in measurements of the continuous-current, agreeably to the proposal of M. d'Arsonval and M. Marey. To attain this end all that is needed is to borrow from electricians their methods and instruments with some small modifications to fit them for their new use. But continuous currents are not the only form in which electricity is used in physiology and in medicine. In fact, their use is rather the exception since it is applicable to only one of the two great aspects of life : *nutrition*. To stimulate *function*, on the other hand, recourse is had to discontinuous currents. In this second case the problem of measurement becomes much more complicated, for the physiologists have not much to borrow from the electricians. Nerve and muscle respond to the electrical stimulus by reactions peculiar to themselves. Contrary to what takes place in inanimate subjects, the nature of the excitation will modify completely the excitability of the living subject, if the excitation does not realise certain physical conditions, the knowledge of which is the exclusive domain of the physiologist. Therefore, to apply electricity successfully in the healing art one must be both a physiologist and an electrician. Living beings are not only sensitive to electricity, but they produce it themselves and by means peculiar to themselves. This *modus faciendi*, which differs from those of the chemist and physician, forms a decided line of demarcation between inorganic physics and biological physics, which latter is a science of very recent date. Finally, the industrial applications of electricity have made a formidable agent of this force, whose effects, comparable to those of lightning, have given rise to accidents, the study of which has the highest interest for physiologist and doctor.

These different considerations have led us to consider that it would be of interest to direct the discussions of the Congress to the three following points :—

1. The comparison of effects obtained by the employment of different medical apparatus ; the necessity of defining the currents used.

2. The nature of the self-produced electrical phenomena in living beings.

3. The effect on living beings of the discharges of the continuous and alternating-current used in the industries.

And as a corollary :

4. The precautions to be taken in electrical installations.

Comparison of Medical Apparatus.

A. *Continuous-Current Apparatus.*—This first point has been settled by the Congress of 1881, which has laid down that the application shall be measured in the practical units, derived from the C.-G.-S. system, namely, the volt and the milliampere. It would be well to add the nature of the electrodes and the area of the surface in contact with the tissues—that is to say, the current density per square centimetre. This is generally useless in physiology where the excited surface is reduced to a point.

B. *Intermittent Current Apparatus.*—This form of appliance is used above all to stimulate the nerves and muscles. Let us see first what is the fundamental law of the electric excitability of these organs. A constant current, supplied by one or two Daniell's cells, for example, causes a sharp contraction of a nerve or muscle each time it is applied to it or taken off. The muscle remains in repose if by the aid of a rheostat the current is made to pass gradually from zero to its maximum value ; but it contracts if a sudden variation in the current is produced. In fact, within the limits mentioned above, nerve and muscle are excited by the variable condition and not by the constant phase of the current. The intensity of the muscular contraction is not necessarily in relation to the energy of discharge of a condenser. The physiological excitation is not defined when we know the fall of potential and the quantity of electricity set in motion. We must know also the time of this fall and its phases, things of no importance in other matters. The curve thus obtained is the "characteristic of excitation." By reducing the time of discharge to one infinitely short, we have evidently only to consider the quantity of electricity set in motion. The discharges of condensers, and the induced current of break in induction coils realise this condition in practice. This condition of instantaneous flow of electricity is only realised in the case of condensers when they are discharged through a relatively low resistance. In exact experiments it is bad, therefore, to try to excite a body of such high resistance as nervous tissue by means of the direct discharge of a standard condenser. A Leyden jar can be discharged through a nerve or muscle without causing the least contraction if the discharge is slowed down by means of a cotton thread. Therefore it is preferable to discharge the condenser through the primary wire of an induction coil. We thus obtain induced currents which are always equal, and which are without direction. It is easy to measure the induced current of break in coulombs by discharging it through a ballistic galvanometer, and comparing the discharge with that of a standard condenser, as I described before the Biological Society in 1884. The difficulty consists in getting an interrupter to give similar breaks, more especially when they are frequent. In my opinion it is absolutely useless to have more than 50 breaks in the second, as this frequency is quite sufficient to cause tetanus of the muscle from the superimposed shocks. The only pattern of induction coil which gives a regular gradation of induced current is that of Siemens and Halske, with movable coils, better known under the name of Bois-Reymond, and which was brought into use in therapeutics sometime since by A. Tripier. From the point of view of numerical graduation this instrument has the inconvenience of not offering a simple relation between the intensity of the induced current and the amount of movement of the coils ; moreover, it is cumbrous when used to excite very sensitive nerves. In certain cases, when exciting the diaphragmatic nerve M. Brown-Séquard and I had to separate the two coils of Gaiffe's apparatus to more than 1·4m. from each other. I have graduated our apparatus in coulombs by means of a ballistic galvanometer. This instrument might with advantage be replaced, in the case of delicate experiments, by one having two-circular concentric coils, whose planes could be rendered gradually perpendicular to one another by a continuous rotary movement. The intensity of the induced current would then be proportional to the cosine of the angle formed by the two planes. A third mode of regulating the induced current would consist in weakening the battery current in certain fixed proportions by the interposition of resistances in the primary circuit. This means is the least perfect of the three, for it alters the duration of the variation of the inducing current, and consequently the duration of the induced. The current from magneto-machines is much more difficult to regulate, for it depends on a number of variables (speed of rotation, the magnetisation of the magnets, the distance of the armature from the magnet, &c.).

To resume the subject of the calibration of faradaic apparatus, all that is necessary in practice is to mark in micro-coulombs the value of the induced current of break, corresponding to each distance apart of the movable coils for a fixed inducing current. These two calibrations could easily be supplied by the maker. The E.M.F. of the induced current varies as the quantity of electricity since the time of induction is constant. Consequently the energy of the induced current varies as the square of the quantity of electricity set in motion. Therefore it is only necessary to mark it for one point on the scale.

The Nature of the Electric Phenomena in Living Beings.

All living beings are the seat of electrical manifestations. Animal electricity has been studied, especially in two tissues, the nerves and the muscles. Nevertheless it is certain that its production is much more general, and that it accompanies all the vital processes. Electrogenesis must be like thermogenesis, a cellular phenomenon due to the same cause—the life-producing combustion due to breathing. Living tissues give rise to two sorts of electrical manifestations which do not seem to spring from the same cause, viz. :—1. The *continuous* electrical manifestations called also currents of repose. 2. The *intermittent* electrical manifestations or currents of action. Currents of action have the remarkable feature about them that in certain cases, as, for example, the electrical fishes, they are capable of reaching a very considerable intensity. Further, these currents do not seem to *pre-exist* in the tissues which are their seat, but to have their origin at the moment when the organ enters on its function.

The laws which regulate the production of continuous currents have been well studied as regards nerves and muscles separated from the body. To study these currents special instruments, with non-polarisable electrodes and dead-beat galvanometers, or Lippmann's electrometers, must be used. We do not yet know for certain if these currents of repose in muscle pre-exist, or if they are due to some circumstance attending the preparation of the muscle—an injury to the muscle. Experience shows clearly that the surface of a muscle *which is perfectly intact*, does not give any evidence of electrical tension, or exhibits only very slight tension. All we can say is that the electric manifestations in muscles and nerves separated from the organism are extremely regular, and are certainly closely connected with the chemical and physical composition of the contractile substance. On this account they have the greatest physiological interest. These differences of potential, which are maintained on closed circuit on the surface of the muscle, are due to chemical action. This is evidently only another way of stating the doctrine of the conservation of energy, but it may be shown in the following experiments that :—

1. The differences of potential diminish in the isolated muscle, *pari passu*, with its excitability ; and when this latter disappears, all trace of the regular current has disappeared also.

2. This current is weakened and momentarily disappears in the anæsthesia produced by ether, that is to say, in the hindering of the chemical function of the protoplasm.

All the continuous electrical manifestations of living matter are not, *in our opinion*, immediately due to chemical action. Continuous currents can be obtained by means of purely physical actions which take place in the body. (i.) By the simple filtration of a liquid without chemical action, across a porous septum ; the converse, in fact, of Porret's experiment. (ii.) By the flow of a liquid in a tube. (iii.) The effects devised by the elder Becquerel under the name of electro-capillary currents, &c.

The intermittent electrical manifestations of which the living tissues are the seat are much more interesting. If we have just excited a muscle by any irritant whatever we shall certainly find :—

Digitized by Google

1. Every point excited becomes negative to the unexcited muscle.

2. That the rapidity of propagation of this negative wave is the same as that of the propagation of the muscular wave (about three metres a second for a muscle of a frog treated with curare).

3. That this negative wave lasts as long as the contractile wave.

4. That the E.M.F. of the negative wave, or of the current of action, may attain the same value as that of repose (·1 Daniell), which it never exceeds.

This current of action (also, but wrongly, called negative variation or oscillation) is sufficiently strong to excite a nerve or even a muscle in which it takes place (the induced contraction of Matteucci). The laws of the current of action in a nerve follow those of the muscle. The E.M.F. of these currents is only weaker than for the muscle (·02 to ·03 of a Daniell's cell in the case of mammifers). The currents of action cannot be put down as the result of the method of preparation, for they can be easily demonstrated at each beat of the heart in the case of man and the mammifers by using the arrangement proposed by Mr. Augustus Waller in 1888. These currents attain an extraordinary intensity in the discharge of the electric organ of certain fishes, the torpedo, gymnotus, silurus, &c. The electricity is not produced beforehand in these organs. They cannot be compared to a battery or a condenser, since in a state of repose they do not manifest any external electrical potential which is comparable to the energy of the discharge. Therefore electricity is produced in these organs only at the instant in which they enter on their functions at the will of the animal. They act from the point of view of the production of electrical energy exactly as, according to M. Marey, the muscle does for mechanical energy. The nervous system no more makes electricity in the electrical organ than it makes mechanical force in the muscle, since the discharges are obtained after the separation of the organ from the nerve centres, just as in the case of muscle. If *contractility* is the property of muscle, electricity (to employ a corresponding expression) is in the same sense the property of the electric organ. No satisfactory theory has up to this time been put forward to account for these currents of action.

M. d'Arsonval has hazarded an explanation, resting on a physical basis and making use of the physical laws discovered by M. Lippmann, which establish a relation in the inorganic world between capillary and electrical phenomena. M. d'Arsonval has shown that a relation of this kind exists between animal electricity and surface tension. All phenomena at present known can be accounted for by this explanation.

THE EFFECTS ON ANIMALS OF CONTINUOUS AND ALTERNATING CURRENTS.—THE ELECTROLYSIS OF TISSUES.—PRECAUTIONS TO BE TAKEN.

Direct experiments have been made on different animals (guinea-pigs, rabbits, dogs), using electricity derived from the following sources:—1. A four-plate Holtz machine charging a battery of four large jars. 2. A battery of 420 volts. 3. Continuous-current Gramme machines of 110 to 8,000 volts. 4. Alternating-current Gramme machines having a mean potential of 300 volts. 5. Induction coils driven by accumulators. From what has been said before, a living being is most sensitive to the variations of the current; therefore it follows at once that for the same potential difference an alternating is more dangerous than a continuous current. Death is caused by electricity in one of the two following ways:—

1. *Direct Action.*—The discharge acts mechanically and destroys the tissues.

2. *Reflex or Indirect Action.*—The discharge acts on the nerve centres, and by irritating them leads to a variety of inhibitory processes known under the names of "*inhibition*" and "*dynamogénée*" since the researches of M. Brown-Séquard.

The static discharge is not fatal unless it strikes the respiratory centre directly with very well placed discharges, whose energy corresponds to about 3 kilogrammetres.

A. Under these conditions the different tissues (nerves, blood, muscles) struck separately by the discharge lose their physiological properties for good.

B. With a battery of 420 volts death is caused by long-repeated interruptions of the current. Death is due to a condition of tetanus, brought on by the current, and is accompanied by a considerable rise in temperature, which is the true cause of death.

C. The continuous-current Gramme machine is not dangerous (at 100 volts) except from the extra current of break. Compound machines have less destructive effect at the same potential, for the second coil serves as a shunt at the moment of break.

With an 8,000 volt machine, a momentary application of the current made the animal (a rabbit) give a great leap, but has not caused immediate death; a second application was necessary.

D. An alternating-current Gramme machine only causes death above a mean potential of 120 volts.

E. A coarse wire extra-current coil is more dangerous than an induction coil, especially if it is connected to a condenser. The danger from a single discharge is defined only by the *electric curve* of this discharge. The knowledge of the difference of potential and the mean current strength is not sufficient: we must know in most cases that which is immaterial in other cases, the duration of the discharge. For equal energy the danger is in inverse proportion to this duration. It is the same for alternating currents, for which we have to take into account the number of reversals per second.

The separation into two groups of the effects produced by high potential electricity has a great practical value in the sense that in the first case death is certain and instantaneous (destruction, with laceration of the tissues), whilst in the second (death by irritation of the nerve centres without destruction) life can often be restored by practising artificial respiration immediately after the accident.

The application to the nerves of a continuous current of low intensity brings on a modification of excitability known as *electrotonus*, into the details of which we cannot enter here. This modification seems to depend solely on the polarisation caused by the passage of the current between the cylindrical axis and the marrow of the nerve, for it does not exist, or only feebly so, in nerves deprived of marrow. The passage of a continuous current of an intensity varying between 10 and 250 milliamperes through any of the tissues of the organism is accompanied by electrolytic phenomena used surgically by Ciniselli, of Cremona, to destroy tissues without the effusion of blood. This valuable method, introduced into France by Tripier, seems capable of giving excellent results in skilled hands. The passage of the current in this case acts as a local caustic, depositing in a nascent condition the acids at the positive pole, and the bases at the negative. In fact, electricity acts the part of a carrier of caustic alkalies and acids, while localising their action to the vicinity of the poles. The cauterisation of the positive pole gives rise to hard and retractile cicatrices. According to Tripier, the contrary would take place in the case of cauterisation by the negative pole.

The current strengths which it is useless or dangerous to use have still to be determined by experiment, but the current may be the cause of general disorders when its strength exceeds an ampere.

ECONOMICAL SIZE OF LINE WIRE FOR CONSTANT-CURRENT CIRCUITS.*

BY B. RHODES.

The writer has for some time been accustomed to use a formula for finding the economical size of line wire for constant-current circuits, and has been requested to present it at this time. With the knowledge that it is not new, and yet that it is needed by many practical electricians, the following is submitted:—

Let X = diameter of line wire in mils.
Let A = length of circuit in miles.
Let B = price of copper per pound.
Let C = cost of power per year per horse-power.
Let E = amperes of current.

When any plant is about to be established B and E are known, C can be determined near enough for our purpose, and A will be found to be immaterial.

$\cdot 016\ X^2$ = pounds of wire per mile.
$\cdot 016\ B\ X^2$ = cost per mile of wire.
$\cdot 0016\ B\ X^2$ = interest and depreciation at 10 per cent.
$\cdot 0016\ A\ B\ X^2$ = annual cost of wire (1).
$\frac{54,577}{X}$ = ohms per mile.
$\frac{54,577\ E^2}{X^2}$ = watts per mile.
$\frac{54,577\ E^2}{746\ X^2}$ = horse-power lost in transmission per mile.
$\frac{54,577\ C\ E^2}{746\ X^2}$ = cost of same.
$\frac{54,577\ A\ C\ E^2}{746\ X^2}$ = annual cost of power lost in entire circuit (2).

It is plain that with any increase in the size of wire the value of (1) will increase, while (2) will diminish, and the economical value of X will be such that the sum of (1) and (2) will be a minimum.

Let u = this sum:—

$$u = \cdot 0016\ A\ B\ X^2 + \frac{54,577\ A\ C\ E^2}{746\ X^2}.$$

$$\text{Differentiating, } \frac{du}{dx} = \cdot 0032\ B\ X - \frac{109,154\ E^2\ C}{746\ X^3}.$$

Placing this equal to zero, and reducing, we have

$$X^4 = \frac{45,700\ E^2\ C}{B}.$$

The formula shows that the diameter of wire depends on the price of copper, cost of power and quantity of current, and is entirely independent of the length of the circuit and the voltage. The differential coefficient shows that the formula is in harmony with Sir William Thomson's rule that "the additional running expense due to the resistance of the conductor shall equal the interest on its first cost." *Price of copper* refers to the bare wire without any covering or insulation whatever. The insulating cover is a mere matter of choice, like a brick, stone, or frame station.

Suppose water power can be furnished at Niagara Falls for ten dollars per horse-power per year and a ten-ampere current generated by this power be used for street lighting in Buffalo, the entire length of circuit being fifty miles, what is the economical size of line wired? A substitution in our formula gives X = 12) mils, equal to No. 8 B. and S., or exactly No. 11 Birmingham wire gauge.

* Paper read before the National Electric Light Association, August 8th, 1889.

ELECTRIC RAILWAYS.*

BY G. W. MANSFIELD.

The application of electricity to street railways has been so rapid that we are liable to lose sight of many valuable points in our herculean efforts to supply the demand. The application of electricity during the past decade has been astonishing. For the transportation of the people in the streets of our towns and cities the demonstration has been witnessed, the application made, and a wonderful luxuriant growth started. Eliminate the horse-car from every city or town in the union and forecast the results. The horse-cars of the City of New York carry 199,491,735 passengers. If to this number are added those carried by the elevated roads, we have the total of 371,021,524, or almost as many passengers are carried in New York City alone as are annually carried by all the steam roads in the whole United States. The street railroads of the State of Massachusetts carry over 44,000,000 more people than all the steam roads in that State. One road alone, the West End of Boston, carries nearly 10,000,000 more than all the steam roads combined. To give you a rough idea of the size of an electric central station needed to operate all the cars. In New York City dynamo capacity of 13,800 horse-power would be demanded, in Boston 9,504 horse-power, and so on. This is destined to come as surely as the days succeed each other. In Boston it has come, and a station of approximately 8,000 horse-power is already in the hands of the engineers.

Electricity shows already the sturdy, vigorous growth that inevitably will result in its complete supremacy.

ELECTRIC STREET RAILROADS.

	1885.	1886.	1887.	1888.	Jan. 1—July 1, 1889.			Total.
					Operating	Building.	Total.	
Number of electric railways..	3	5	7	33	19	42	61	109
Number of miles of road	7·5	28	29	130·5	113	267	380	575
Number of cars.	13	39	81	265	174	364	538	936

The figures of the table certainly show that the facts warrant the prediction. They were most carefully prepared and include every road of any record. It does not show it all either. That remarkable contract which the West End Street Railway Company of Boston, the largest street railway company in the world, signed recently with the Thomson-Houston Electric Company is not included under the heading "roads building in 1889." I think that this contract in responsibility and importance is one of the greatest that has ever been signed in the history of electricity. In electric railroading it is the greatest and probably will be for many years to come. The West-End Street Railway Company, of Boston, owns 217 miles of track, and 1,584 cars, all of which are to be equipped so as to be operated with electricity. Add these to the list, and how does our list stand? If it be within the bounds of the supply men, at least 75 miles will be built this summer and 100 or more cars equipped.

In meeting this demand for better transit there are many considerations that claim our most careful attention. The conditions to be met are widely different from all other electrical applications. Essentially we have first, a steam engine; second, a dynamo; third, a conductor; and fourth, a motor mounted upon a vehicle, and subjected to mechanical and physical conditions more extreme and severe than ever heretofore has been imposed upon any piece of electrical machinery. In the battle for success the engine has to stand the bulk of the fighting. Anything wrong with it affects directly the electric system, and in many cases it also has to stand the blows if anything is wrong with the electrical system. The extreme liability of short circuits on the road from a variety of accidents that may happen on the very best roads render of the first importance that the engine have its main moving parts at least 20 per cent. heavier than ordinarily. Under the extreme fluctuations of load, keys, nuts and bolts will work loose. An engineer in a large station recently told me that he practically took to pieces and put together nearly every month a 100 horse-power engine running an 80 horse-power dynamo, whereas prior to the time that it had been connected to a railway dynamo it had given practically no trouble, although worked well to its capacity.

A compound engine rated at 109 horse power, running an 80 horse-power dynamo under test recently, gave the following:—

Friction card with dynamo, but no current, 11·65 horse-power.
Aggregate horse-power of cards, 1,247·74 horse-power.
Average horse-power of cards, 56·67 horse-power.
Maximum card, 120·79 horse-power.
Minimum card, 15·56 horse-power.

The cards were taken at 10 minute intervals for four hours. There were at the time three electric cars on the line, each towing another. As the day was a pleasant Sunday, every car was crowded. During the same time current and potential readings were taken on the line at the station. The average gave 30 horse-power, or an average efficiency of 54·6 per cent. for the total time. Every moment deducted that no current was flowing would raise this efficiency. At times the efficiency was far higher than this. The road conditions were severe, the grades ran as high as 10 per cent., and had numerous others of 5 and 7 per cent. The extreme current fluctuations were noted in one minute's variation from 45 amperes to 140. The potential was very constant. On another small road the extremes varied from the friction load to nearly 85 horse-power on an 100 horse-power engine. These extremes would happen even during the time a three-impression card was being taken. Under such conditions the questions of coal economy is a troublesome one. On large roads, unquestionably a far better showing would be possible. Laying aside the question of coal economy, which is cheap in comparison to food for horses, the best engine is the one that handles the average work with the least repairs. On some small roads the ratio of engine friction to average daily load may be large. The great majority of roads, however, will have a sufficient number of cars to so reduce the ratio of extremes to the average load that the engine can work at its most economical point of cut-off the major part of the time, and raise the average load to such a point above the friction load that the per cent. lost will be comparatively small.

If the following facts are known a fair judgment can be made as to how much electric power must be allowed per car, although I am much afraid that the accuracy of the judgment would not be that of a William Tell:—1. Number of cars simultaneously operated. 2. Speed and nature of service. 3. Maximum grade and number of grades. 4. Scheduled location of cars in reference to grades. 5. Motor cars to be used to tow other cars or not. 6. Any peculiarities in regard to the distribution of cars. 7. Condition of track. 8. Location of track in reference to power house.

A moment's thought over any one of those points, I think, will convince you of its importance. On a portion of the Cambridge division of the West End Street Railway Company's road, of Boston, the Thomson-Houston Company's motors commenced running February 16, 1889. Up to July 1, 165,781 miles and 25,505 round trips had been made with a loss of but 325 miles, or ·19 of 1 per cent., and 49 round trips, or the same per cent. of loss. During this time nearly 1,500,000 passengers were carried. This, in view of the fact that during the entire time one, and part of the time two, tow cars were drawn, is remarkable. It must also be known that the route extends over one of Boston's most crowded business thoroughfares, and is the main street connecting Cambridge and Boston. On a portion of the route there is an open bridge about 1,800ft. long, on which is located one draw, which is opened from 20 to 30 times a day. Over this bridge 1,810 cars per day pass, or on the average of one every three-quarters of a minute, and at some portions of the day they run at half-minute intervals. The teaming on this street is also very heavy, necessitating constant stopping. You will see from these figures what the loss of current or a motor burn out causing delay would mean. The record, however, has been magnificent. As the dynamos are run by the Cambridge Electric Light Company, and are so arranged that the same engines furnish power and lights for their own purposes, as yet only approximate data as to the fuel consumption, &c., has been possible. A few electrical tests have been made, as well as it were possible. Ammeter and voltmeter readings were taken at the stations every 15 minutes, four readings per minute, or at 15 second intervals. This was kept up from 6:30 a.m to 12:30 a.m. next morning for five days. In all, 1,480 readings were taken. The average of these readings gave for 12·6 cars in continuous service, 111·6 amperes, 500 volts, or 74·8 horse-power. Per car this is 8·8 amperes and 5·9 electrical horse-power. The average number of passengers carried was about 58 per round trip. We now have 32 cars in operation, and observations, in so far as they have been taken, show a marked decrease in horse-power per car. At Richmond, Va., some rough tests gave the electrical horse-power required per car at the station as from 4 to 5. On the road to Lafayette, Ill., the figures of Dr. Bell show the remarkable low figure of 2·5 electrical horse-power. There are a number of circumstances on this road that would tend to make this figure so low. The cars are smaller than those ordinarily used, and I should judge that there were other circumstances entering into the calculation that would tend to reduce it. However, it well shows, possibly, one extreme in railroading. The other extreme might be cited in the case of the Lynn road, Highland division. Here only one car is in operation. In the course of its route it ascends a hill graded at the rate of 8·7 per cent for 300ft., and immediately passes down on the other side. In this case the engine was indicated. Five cards were taken when the car was ascending the grade, the average of which was 52·2 horse-power. If we allowed a dynamo efficiency of 90 per cent., this would indicate an electrical horse-power of 47 horse-power. This is unquestionably a very extreme and exceptional case. I might add, incidentally, that the car pays handsomely. At Plymouth, Mass., a road having many heavy grades, the maximum being over 10 per cent., and operating but three electric cars, each with tow cars, the electrical horse-power at the station per car was approximately 7·72 horse-power. On the cars the extremes vary obviously according to speed, grades, load, &c. It frequently reaches from four to five times the average value during the total time. In Lynn the variation is enormous. In Cambridge the current frequently rises to from 65 to 70 amperes, or about 42 horse-power. Especially is this the case on starting. You can see from these figures the impossibility of giving only the most approximate figures in this direction unless every detail as to operation and conditions are known. I feel, however, that on roads having no grades over 5 per cent., and operating under 10 motor cars with tow cars, 15 horse-power per car would be a safe figure for dynamo capacity. On large roads this figure could be reduced to 12 and possibly 10 horse-power per car, while on small 3 or 5 car roads with heavy grades 18 or 20 horse-power might not be any too much. At Cambridge tests show that, of the total time consumed by a car in a round trip, it was taking power only 61·8 per cent. of the time, and that 6·7 per cent. of the total time the car was stopped. At Washington, where the streets were freer and not so thickly populated, the above figure for time when power was used rose to 66 per cent. Neither of these roads are what you might call large. It seems, however, that from 30 to 40 per cent. of power in excess of the absolute requirements can be planned for. I do not think, however, that this can be implicitly relied upon as in other power business, since there are many factors in the general operations of a railroad system that might at any moment tax the central station to its utmost.

In regard to total electrical and total commercial efficiencies, it is impos-

* Abstract of a Paper read at the meeting of National Electric Ligh Association, August 8, 1889.

Digitized by Google

sible for me or anyone else to give accurate figures. There are so many fluctuating factors entering into such a determination, that, whereas a test made to-day would give me certain figures, a test made to-morrow, or a week later, would give me entirely different figures. The time factor must enter largely into such a test. From estimations based upon many figures, I feel certain that a total electrical efficiency of at least 70 per cent. can be obtained, and a total commercial efficiency measured from the indicated horse-power of the engine to the car wheel horse-power (W.H.P.) of from 45 to 50 per cent. If the road-bed, rolling-stock, and all the electrical apparatus is maintained as it should be, I see no reason why this figure cannot be exceeded.

There is one point which is of vital interest to the managers of electric light companies, and this is how they shall charge the railway companies for the power which they desire. I have already shown you that it is an exceedingly difficult thing to estimate upon the requisite power, as the conditions are so fluctuating and so variable. After, however, the question of the amount of power has been settled, the next point to determine is whether they shall charge the railway company by the hour, by the day, or by the car mile. We have a large number of roads already hiring power of local companies; all of the methods just mentioned are in use. Upon small roads where the schedule of the railway company is such that they have only a few cars running continuously, meeting emergencies by extras, and where the grades are heavy, a satisfactory basis has been to charge so much per day per car, the price ranging all the way from $3 to $5, $6 and even $7. When the roads are of moderate size, or are subject to many variations and sudden demands on the part of the public for better facilities, or when the line runs to some resort and the main bulk of business lay in picnics, &c., charges on the hour basis is sometimes preferred. This price varies from 15 to 30 cents per hour. On larger systems, where the schedule is definite and fixed, the mileage basis is the preferable by far. The prices on this basis range from two to six cents. You can readily see that if the cars ran at infrequent intervals, and if the morning and evening traffic was especially heavy and required a larger number of cars, while during the major part of the day only a few cars were out, the mileage basis would be quite unsatisfactory, since on the whole you would have to make steam possible for the maximum railroad output, and maintain it throughout the day. All of these estimates, however, can only be determined by knowing the local conditions and circumstances.

There are some 1,600 central electric light stations already located throughout the country, and some 425 railroad companies that sooner or later will be obliged to have electric power. Is there any reason why you should not do it? I know of many a station that has to stint and save to tide over the year's dull seasons. Here is an opportunity for still one more chance at profit. Railroads have an older and better standing in the financial world and on the money market than electric light companies. Can you afford to let the opportunity go by? From careful research, my own judgment would be that in many cases it would be the company's salvation.

A METHOD OF MEASURING THE COEFFICIENT OF SELF-INDUCTION BY MEANS OF THE TELEPHONE.*

The German Imperial Telegraph Department has been engaged in studying a practical method for measuring coefficients of self-induction which does not require a highly trained electrician to work it. The method is based on the Wheatstone bridge, a telephone being used instead of a galvanometer, and the apparatus used serves not only for the comparison of coefficients of self-induction, but also for determining their absolute value.

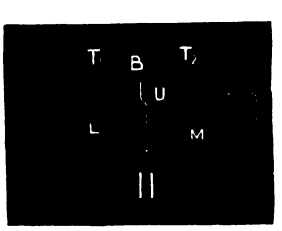

FIG. 1.

When the resistances T_1, T_2, M, L in the arms of the bridge (Fig. 1) have been adjusted to obtain a balance no current flows in B, and therefore this circuit may be opened or closed without affecting the currents in the rest of the system, and, consequently, if telephones are used for the resistances T_1, T_2, they will be silent on making and breaking contact at U.

Now, in using this method to measure self-induction, T_1 and T_2 (Fig. 2) are the coils of a differentially-wound telephone. The resistance of these coils is equal, and very great compared to the resistances of M and L, which are also equal to one another. The resistance of B is very small. A contact breaker is placed in the battery circuit, and B is permanently closed; the telephone will now emit a sound, unless the coefficients of self-induction of M and L are equal. These may be made equal in the following manner:—

* From *La Lumière Électrique*.

The two equal circuits of a double-wound coil S_1 are inserted in the arms T_1 and T_2, and opposite this double coil is a coil S, which is in circuit with the battery and contact breaker. The coils S and S_1 are mounted on the same support. S is fixed, while S_1 can be moved in the plane of S, and rotated about an axis in that plane. Now, the intermittent current flowing in S induces the same current in each half of S_1, and the intensity of it is proportional to the sine of the angle between S and S_1. Let us suppose that the coefficient of self-induction of L is greater than that of M. The action of M is partly neutralised by that of L, and the two coils, S and S_1, can be made to compensate the rest by suitable adjustment. If the coefficient of self-induction of M is very small, the value obtained by adjusting the coils S and S_1 is practically the coefficient of L.

By means of a galvanometer the calibration of the instrument and the measurement in absolute value of the coefficient of mutual induction between the coils S and S_1 are easily effected.

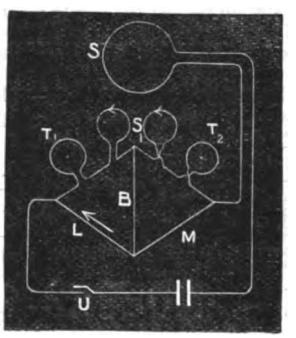

FIG. 2.

With an instrument constructed under the direction of Herr Stecker very good results have been obtained in the measurement of the coefficients of self-induction of steel and bronze wire. Iron wire does not give such a good result, for the telephone is never silent, and it is the least sound which has to be taken. An attempt has been made to measure the coefficient of self-induction of an iron wire forming part of the Berlin telephone system, but it has not given satisfactory results.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 17, 1889.

The National Electric Light Association has just held its tenth semi-annual convention at Niagara Falls, and the meeting appears to have been of a most interesting and successful character. The questions which come up before such a body are not strictly of a scientific nature, but there are a great many practical issues which have to be settled, and upon these the members threw themselves with a great deal of energy and sound common sense. Thus, for example, the Association has been quick to see that all this talk about the danger of electricity, and the legislation which proposes to inflict the death sentence by means of the electric current, is extremely hurtful to electrical industries as a whole, and it has determined to enter its protest against any measure which shall tend to turn the dynamo into an instrument of torture. The question of the constitutionality of execution by electricity was brought up at the Niagara Falls meeting by Mr. F. A. Wyman, a lawyer, of Boston, and Dr. Otto A. Moses, of this city, and after they had been heard on the subject, resolutions were adopted urging the Governor of the State to suspend sentence, and petitioning the State Legislature to repeal the electrical execution law. In the course of his remarks on the subject, Dr. Moses presented a number of interesting statements elicited by circulars sent to some 800 managers of electric light stations, and it would appear from these replies that the sensations experienced by those unfortunate enough to get a severe shock are of the most painful and distressing nature. Of 73 accidents occurring in central stations, 54 were due to the continuous-current and 19 to the alternating, and since in each of these cases a heavy current had not been strong enough to cause death but had given rise to dreadful sensations, it seemed fair to argue that in inflicting death, torture would be superadded in a way most repugnant to modern ideas of

Digitized by Google

decency and humanity. It is hoped and believed that electrical execution has been removed from the list of punishments by this and similar action on the subject.

Another topic of general interest upon which the Association took action was with regard to abolishing the custom duty on copper ingots, wire, plate, sheet, bar, and rod. The resolution on this subject was presented by Mr. C. A. Brown, representing the Western Electric Company of Chicago, well known as one of the largest manufacturers of electrical apparatus in this country. It was seconded by Mr. G. M. Phelps, who stated it as his impression that copper entered into the cost of electric light plants in general to the extent of at least one-third, and perhaps more. It was endorsed by President Weeks, who, announcing himself from the chair as a Protectionist, said he believed this was a case in which we should protect ourselves, not against our foreign cousins, but against our home friends and relatives. The fact would appear to be that there is no advantage to any industry in the imposition of the copper tariff, and since everybody would be bettered by the supply of cheaper raw material, whether from abroad or from our domestic mines, the Association puts itself on record as desiring Congress to abolish the customs duty in question. Another interesting topic of large interest touched upon was that of the insurance of electric light plants. There has been a great deal of comment on the part of electric light men against insurance agents and companies, because good central stations have been lumped with bad, and the whole class rejected as an undesirable risk. The report presented by Mr. P. H. Alexander showed that 172 insurance companies had been paid premiums of over $41,000, on nearly three millions of insurance in 1888, while the losses collected during that year were less than $22,000, showing a gain to the insurance companies of $19,000. In the year following the amount of insurance in central stations was $3,000,000, the premiums received were $51,000 odd, and the loss was only $11,000, leaving a good balance to the insurance companies. Mr. Alexander drew attention to the work of the New England Insurance Exchange, which had issued a form describing a model electric light station which the Exchange guaranteed to insure at a very low rate; and the remarks of the insurance men on the matter, after the presentation of the report, went to show that the work of the Exchange, aided by the New England Electric Exchange, had resulted materially in raising the standard of central light station construction in New England. As Mr. Barton said:—"The work of perfection seems to have taken the strongest hold with us, and every electric light company that is contemplating building stations to-day is trying to do it in accordance with the standard which we have established, and some of them are even going past our standard." The committee in its report suggests the formation of an organisation within the Association for purposes of mutual insurance, but this idea did not seem to find general favour, on the ground that a thoroughly satisfactory station would be insured by the regular companies just as favourably as it would be by any mutual organisation, which, on the other hand, for its own sake, would have to be severe with stations that do not come up to its requirements.

Turning to Papers of a more technical nature, two that deserve note are those of Mr. M. D. Law, of Philadelphia, on the theoretically perfect arc-light station, and that by Mr. J. T. Henthorn and associate, on the new central station of the Narragansett Company, at Providence. Mr. Law's station at Philadelphia, of which the Paper gives a pretty good idea, does one of the largest electric light businesses in the country, and it is well known amongst electric lighting men here for the economy and efficiency with which it is carried on. The remarkable fact was brought out that Mr. Law had had two Corliss engines in his station which had been running steadily for 7 years, with a loss of only 10 minutes from trouble, and with an expense of only $25 for repairs. This is a remarkable statement, but nothing in the subsequent discussion tended to upset it, and it was realised that Mr. Law had made out a good case for the use of large slow-speed engines in central stations of the arc-lighting class. The Paper of Mr. Henthorn described what will be one of the finest arc-light stations in this country. Mr. Henthorn is in favour of running his station with large slow-speed engines, holding them to be more economical in the long run, in spite of their somewhat larger first cost. Perhaps the neatest criticism on this magnificent new station was that made by Mr. Kerr, a representative Westinghouse engine man, who said that the design was not sufficiently elastic. The station was a monumental piece of engineering work; but he did not think the time had yet come when we could build electric light stations as we did waterworks. There is some point in this comment, for as Mr. Kerr pointed out, electrical discoveries might be made very shortly which would seriously impair the utility of the station, and it would cost so much money to change it that it never could be changed. Yet, on the other hand, it is to be regarded as most happy that the time has come when electric light stations can be built on such a scale, and with such finish and refinement, for in this manner the development and growth of the business is perhaps brought more forcibly to the attention of capitalists and of the public than in any other. In connection with central stations also an interesting paper was read by Mr. C. C. Haskins, the electric light inspector of Chicago, who gave some point to the moral that incessant testing is the price of efficiency in central station apparatus. Mr. Benjamin Rhodes, of Niagara Falls, presented a neat little Paper on the economic size of line wire, in which he gave a method of calculation and developed the fact that the diameter of the wire to be used depends on the price of copper, the cost of power, and the quantity of current, being entirely independent of the length of the circuit, and, in this case, of arc-light currents of the voltage. The formula worked out agrees, too, with Sir William Thomson's rule for the most economical size of conductor, and with the contention of Deprez that the diameter is independent of the length of the circuit. Aside from the general interest attached to this little Paper a special interest was given to it by Mr. Rhodes using the Niagara Falls as an example. Supposing water power be furnished at Niagara Falls for $10 per horse-power per year, and a 10-ampere current generated by it, to be used for street lighting in Buffalo, the entire length of the circuit being 50 miles—25 miles each way—the economical size of line wire to be used would be No. 11, Birmingham, wire gauge, or about half the diameter of an ordinary lead pencil. This is a practical deduction that some of the members were not prepared for, as the general idea is that to transmit the power of the Niagara River to Buffalo would take a wire a great many sizes larger than that. Two interesting Papers were presented on street railway work, one by Mr. George W. Mansfield on the subject generally, and the other by Mr. William Bracken, speaking for storage batteries. Mr. Bracken called attention to the fact that the Julien cars on the Fourth Avenue-road were in successful operation, and that the number was being constantly added to. Mr. Mansfield presented a vast mass of most interesting statistics, in which he showed the rapid growth of electric railroads. He states that at the present time there are in this country 109 electric railroads operating and building, with 575 miles of track and 936 cars, whereas four years ago there were only three roads with seven miles and thirteen cars. These latest figures are exclusive of the enormous contract just made with the West End-street Railway Company of Boston, which, owning 217 miles of track and 1,584 cars, proposes to operate its whole system by electricity. The point that Mr. Mansfield made was that it was worth the while of electrical men all over the country to see what they could do to take part in the development of this industry. He figured out that in New York City to operate the street cars by electricity a dynamo capacity of 13,800 horse-power would be demanded, and in Boston 9,504 horse-power. This, he said, was destined to come as surely as the days succeeded each other; in Boston it had already come, as a station of approximately 8,000 horse-power for electric railway work was now in the hands of the engineers. He pointed also to the fact that there were now some 1,600 central stations throughout the country, and some 425 railroad companies, that sooner or later would have to use electric power, and he wanted to know why electric light men should not take hold of this business, and get their share of its returns, either by running independent stations for that class of work or by supplying the current. Supplementary to this topic was the resolution offered by Mr. Lynch, inviting the electric railway companies to standardise their potential as

Digitized by Google

much as possible, so that there may be more uniformity in this respect than now obtains in the matter of lighting.

The quarrel between the Postmaster-General and the Western Union Company with regard to the rate of one mill per word, which it is proposed the Government should pay for its business is still going on, and Mr. Wanamaker and Dr. Norvin Green are exchanging excellent argumentative letters on the subject. The absurdity of the position of the Government is clearly shown in one fact, the statement of which renders it quite unnecessary to go further into questions of legality and constitutionality. If the Western Union Company were compelled to do the whole of its business at the rate that Mr. Wanamaker has attempted to fix for Government messages, its receipts for the year's work would be $257,320. The expenses of the Western Union Company during the average year are just short of $15,000,000, so that on Mr. Wanamaker's theory, the Government would have the right to make the Western Union Company spend $15,000,000 to earn a sum of only one-sixtieth of that amount. Mr. Wanamaker may talk as he likes about agreements under the Act of 1866, &c., but the logic of these figures is convincing.

New York City is at the present "torn up" and greatly agitated over the question of the World's Fair, which it is proposed to hold here in 1892, to celebrate the discovery of America by Columbus in 1492. It has been variously suggested to hold this exhibition at Washington, Chicago, St. Louis, and other places, but the choice is gradually narrowing down to New York City, and remarkable activity is being shown in preparing for the work. The Mayor of the city has invited the co-operation of a large number of well-known men, and has already appointed various committees to take action in making the preliminary arrangements. Various electrical bodies in this city are already up and doing, and each of these has a man to represent them on these committees. It seems probable that a representative will be allowed to each of the great electrical departments. The American Institution of Electrical Engineers is manifesting an early activity, and has already taken preliminary steps not only to assist in the great work, but to hold an international electrical conference in this city, taking up the work where the Paris conference may leave it. The co-operation of electrical bodies all over the country is to be invited, and there is no reason to doubt that the conference in 1892 will be one of the most interesting and useful of the series.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *August* 27, 1889.

On the 25th inst. the new telephone exchange in Prague was opened with a new and improved multiplex switch-board, made by Mr. Otto Schaffler in Vienna. The old boards were in use until five o'clock in the morning, and at 6.30 all the 615 subscribers were transferred to the new board. The whole of the new arrangement was installed whilst the old continued in service. At ten on the 25th the official opening of the new service took place. The Governor of Bohemia, the Burgomaster and Town Council of Prague, the Post Office head officials were present or represented, and were shown the new Exchange by the company's general manager, Mr. R. Howard Krause, and all expressed their delight and approval of the new arrangements.

In about a fortnight the new Government trunk line from Vienna to Prague will be completed, and the subscribers in Prague will then be able to speak to the subscribers in Vienna. The main line is already finished, and only the section through the town remains to be completed.

The Austrian and Hungarian Governments have finally come to an agreement with regard to a telephone line connecting Vienna and Budapest, a distance of over 150 miles, and work is to be commenced immediately, with a view to the wires being ready by the end of October. The Austrian Government will erect the line up to the river Leitha, while the Hungarian Government will complete it to Budapest. Three wires, two of which are to be reserved for Stock Exchange messages, will be run to begin with. The subscribers to the Vienna and Budapest exchanges will be able to communicate with one another direct, the price for three minutes' conversation being 1fl.

A Viennese electrician, Herr Capilleri, has obtained a concession for the electric lighting of the western faubourgs of Vienna. The site of the proposed central lighting station has been approved by the officials, and the work of construction has begun.

CORRESPONDENCE.

ALTERNATING MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The leaderettes in your issue of the 16th call for a reply from me; but as the post to the West Highlands is slow, I fear this letter will be too late for your next.

Before treating the various points in order, let me say that you appear to me to be trying to put a theory into my mouth, for which I am in no way responsible, and with which I do not agree. You appear to think I am an advocate of the curve of sine and constant co-efficient of self-induction method of treating motor problems. This is not the case at all. I regard such methods as a convenient for getting a rough result, but nothing more. I prefer to trace the action of the armature current on the field-magnets and pole-pieces, and not to assume a constant co-efficient of self-induction. The only excuse for including these reactions in the comprehensive but loose expression, "self-induction," is that it admits of the application of the curve of sine method to see roughly whether a motor will mote. The term "self-induction" has been often used in connection with direct-current machines to denote what I prefer to call the "back induction," or the demagnetisation of the field by the armature current. I have often objected to this term, and without wishing to insult anybody, I would suggest that the term was used in direct-current work only by those who did not really understand what takes place. Though one cannot reasonably talk of the back E.M.F. due to the self-induction of a direct-current armature, it may be permissible to call the "back induction" or the field demagnetisation of an alternator the "self-induction," and when you can get a rough approximation to truth by such an assumption, the curve of sines and constant coefficient method may be used. Of course in really thinking of the armature it is clear that its instantaneous coefficient of self-induction depends on what is going on outside it, that is, in the field magnets and pole-pieces.

Turning to your leaderettes and taking the points in order, I do not say "that the old theory of synchronism stands in need of no modification whatever," but that two machines of equal E.M.F. cannot run as dynamo and motor if the current at any instant is equal to the resistance divided by the algebraical sum of the E.M.F.'s; the machines would have in these positions an open circuit. That is to say, the machines cannot work unless the armature currents affect the fields, or unless, in other words, there is self-induction. I do not mean to say that the insertion of external self-induction has exactly the same effect as alteration of the fields. I do not see how the question of Dr. Hopkinson's infallibility comes in. He proved that with certain assumptions, admittedly only very roughly true, machines would run as dynamo and motor; and his conclusions are, roughly speaking, correct. From this people generally assumed that alternating motors were perfectly practicable if they could only be made to start. As far as I know I was the only writer who strongly urged that starting was only one difficulty, and that the efficiency at varying loads must be low. As I say, I do not know whether I was alone in this or not. I see from your note in the issue of August 9th, that M. Leblanc insists on the inefficiency of synchronising motors. I am taking a holiday now, and have not read the article itself. Mr. Mordey, of course, makes out that an alternating motor has the same efficiency as a dynamo even when designed for varying loads; that is, made so that its open circuit E.M.F. is equal to or greater than the generator or main E.M.F.

As to the statements of mine made between 1887 and 1889—which you now know to be hopelessly at variance with facts, and which resulted from my own, or at least the old, theory—I will take them in order:—

1. "That coreless armatures would only run parallel with no load." Such machines were supposed to have very small armature reaction, or very little self-induction. No doubt I, with others, have under-estimated this, but that is not a result of any theory of synchronisation. I must also point out that we are not at one as to what is meant by running in parallel. All these alternators have some tendency to synchronise. If ma-

Digitized by Google

chines are at full load their armature loss is as high as is safe as regards heating. If they are out of step, due to one engine having more steam, so as to give greater torque, the armature loss is increased. What is required is to get the greatest corrective torque with the least extra armature heating. If the armature heating is great enough to cause trouble when the engines vary as much as they do in commercial work, the machines cannot work commercially in parallel. I believe that Mr. Ferranti has found this to be the case with his machines, but am not certain. I know of no case of such machines running in parallel. Of course, it must be borne in mind that the corelessness of the armature is in itself of no importance. The real question is whether the armature current can weaken the field of the motor or not. There is much more difference between a Zipernowski and a Westinghouse machine than between a Westinghouse and a Mordey.

2. "That with such armatures, it would be necessary to make up for the lack of self induction by putting iron elsewhere in the circuit." In such cases, I should still put artificial self-induction in the circuit; not "iron," but a "choking coil" which would probably contain iron.

3. I laid great stress on the "induction coupler," and still believe in it for keeping machines in parallel.

4. "That with a parallel constant E.M.F. system of supply, the use of such synchronising motors was incompatible with efficiency." This I still maintain. You say you know these conclusions are hopelessly at variance with facts; but how do you know that? Have you ever measured the virtual current of a parallel motor at full load? Of course, if the armature loss as a dynamo or resistance is, say, two per cent., the armature loss as a motor might go up to four or five per cent. without being easily traced in a rough experiment. The virtual current must be taken, to give an accurate result, and to give a fair comparison the total armature loss must be kept down to the value at full load on resistance. Vague statements that machines run well as motors without measurements of current are of no value.

5. "That such motors would not work well with varying load." An ordinary motor can be made to work well at full load by weakening the field till it is approximately cophasedly synchronised; but such a motor cannot have its load taken off, or it will lead and tend to short-circuit the mains. The armature loss will increase as the load is decreased unless the armature current now strengthens the field considerably. This form is, therefore, unavailable for varying loads; and resort must be had to a motor which at no load gives the same E.M.F. as the generator, or for safety, a very little more. Such a motor at full load has its current and back E.M.F. differing in phase, and is therefore inefficient, the armature loss being high in proportion to the output. It is here that, I take it, I differ from Mr. Mordey and from you.

Your next paragraph about the time-constant varying with the vibration frequency cannot be dealt with as it is vague. What is meant by Mr. Mordey's machines synchronising "equally well" at any "periodicity"? For example, two machines might be run at 100 volts and 1,000 revolutions, and at 100 volts and 500 revolutions, and might be arranged with similar fields in each case, or with one field slightly altered so as to get the same angular lag in each case. Or they may be run at 100 volts and 1,000 revolutions and 50 volts and 500 revolutions with equal fields or equal lag. Then how is the "equally well" measured, and what does it mean? Does it mean that the difference of torque is the same, or that the ratio of the difference of torque to the whole torque is the same, or that the virtual current, and therefore the armature loss, is the same? These general statements give no information. Until the alleged phenomenon is stated with some symptoms of scientific accuracy I cannot offer any explanation. I can only say that if the machines are in all cases running so fast that the field and pole-pieces do not vary their magnetisation perceptibly every half period, I should take L as constant. I should prefer not to take L at all. Your statement that L has been shown to be unchanged is misleading. You probably refer to some experiments with secohmmeters. I have already said that does not give you a value for L for a moving machine at full load, and I object to your trying to confuse by using such an obvious logical fallacy.

You next try to make out that I rudely controvert Sir William Thomson. This is not the case at all. Of course Sir W. Thomson's explanation is correct, but I still repeat that "most of the conclusions drawn from it must be reversed to have any meaning." In this experiment the motor field was strengthened and the dynamo weakened; in parallel work the motor field is weakened and the dynamo field strengthened. In the experiment the armature-current increases as the load decreases, in parallel work the reverse is the case. In the experiment the motor was leading, in parallel work it lags. Do you hold that it was generally understood, before I called attention to the fact, that the 2,000 and 1,000 volt experiment referred to a series motor and not to a parallel motor at all? As to contradicting people, if there is anyone whose opinion I generally respect, it is Mr. Mordey.

You go on to say that you do not so much differ as to my present interpretation of Mr. Mordey's experiments as to my assumption that I knew all that is to be known before. I do not see that my present interpretation is different from my past interpretation. Nor have I said that I knew all that was to be known. There is an irresponsible rashness of statement about your assertions that would adorn the pages of a society journal. Again, I am not crying down a new discovery. You here beg the question. I deny that Mr. Mordey has made any discovery. If he has, what is it? You also say I am illogical because I acknowledge I do not understand what Mr. Mordey's opinions are. If you say twice one is three I can controvert your opinion, without knowing how you prove it. All I need to do is to give my reasons for supposing the result to be approximately two. I have said clearly that the current and E.M.F. are not the same in phase in a parallel motor, therefore the armature loss is higher in proportion to the output than in a dynamo. Mr. Mordey denies this, but does not say how the motor works. You, as far as I can follow you, agree with Mr. Mordey, but you do not say either whether in a parallel motor the current and back E.M.F. are the same in phase, or how the motor can give the same efficiency if they are not.

Of course, any young fellow under fifty would forgive the bad taste of personal remarks about his extreme youth in view of the great value of fatherly advice from the venerable Nestor of Salisbury-court.—Yours, &c., JAS. SWINBURNE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the letter of mine which appeared in your impression of August 16th, obviously my remarks *re* the effect of iron in the armatures of alternate-current machines apply only to those machines which have either Pacinnotti teeth or projections around which the coils are wound, and not to those with a continuous smooth core, such as is used for a Gramme armature.—Yours, &c., W. B. SAYERS.

PORTABLE POCKET AMMETERS AND VOLTMETERS.

Some neat pocket ammeters and voltmeters have recently been brought out by Messrs. Mayfield and Co., of Queen Victoria-street. These instruments, which have been specially designed to meet the requirements of those engaged in electric lighting work, are shown in full size in the above cuts. The solenoid is wound on the segment of a circle, having for centre the centre of the case, and the core is tapered, so that the pull is very nearly proportional throughout, the opposing force being supplied by a delicate spiral spring. The pivots supporting the hands work in jewelled centres. The instruments are mounted in nickel-plated cases, and can be used in any position. The deflection for 1 volt or 1 ampere is about 50deg. in the smaller sizes, so that considerable accuracy can be obtained in the measurement of small currents. The ammeters are made in two types, one measuring currents up to 5 amperes, and the other currents of from 10 to 50 amperes. The voltmeters are made in three sizes, from 1 to 5 volts, 10 to 50 volts, and 20 to 100 volts.

NEW COMPANIES REGISTERED.

THE ALCOY AND GANDIA RAILWAY AND HARBOUR COMPANY (LIMITED).—Registered by Ashurst, Morris, Crisp and Co., 6, Old Jewry, E.C., with a capital of 525,000 in £100 shares. Object, to take over, construct, acquire, equip, maintain, and complete works, railways, and harbours in the kingdom of Spain or elsewhere, and for such purposes take over, hold and exercise all or any of the rights, privileges, of any authority, concession or concessions, for the construction, equipment, and working of the same, and to enter into and carry into effect any contracts, and to maintain and work any other railways, tramways, electric or other power, telegraph and telephone lines and works, or other means of communication or appliances of a similar nature in the kingdom of Spain or elsewhere. There shall not be less than three nor more than five directors. Qualification, £500. The first to be appointed by the subscribers to the memorandum of association. Remuneration, £1,100, of which £300 shall be allowed to the chairman, and the balance divided among the other directors as they may determine.

STANHOPE WATER ENGINEERING COMPANY (LIMITED).—On the 17th inst. this company was registered, with a capital of £25,000, divided into 1,000 6 per cent. cumulative preference shares, and 4,000 ordinary shares, of £5 each. It proposes to enter into an agreement with J. S. Sawrey and Harrold Collet, for the acquisition of inventions relating to the supply or purification, softening, or filtration, of water, and for dealing with sewage, dye waters, refuse, or polluted water. Power is also taken to carry on the businesses of civil, mechanical, electrical and telephone engineers, and of chemists and contractors. The number of directors is not to be less than two, nor more than five. Qualification, £100 in shares. The company in general meeting will determine the remuneration.

CITY NOTES, &c.

BIRMINGHAM COMPRESSED AIR AND POWER COMPANY.—The ordinary half-yearly meeting of this company was held this week, and Mr. H. Wright, who presided, stated that the mains now laid, ranging from 24in. to 7in. in diameter, extended to four and a-quarter miles. Fourteen works were now supplied with power, and many more were negotiating. Their customers expressed complete satisfaction. He further stated that 5,000 clocks and 8,000 electric lamps derived their motive power from compressed air in Paris alone.

NATIONAL TELEPHONE COMPANY (LIMITED).—This company notify that their share register will be closed from 23th inst. until 2nd prox., both dates inclusive.

THE SCHMIDT-DOUGLAS ELECTRIC COMPANY.—An order for liquidation has been made in the estate of this company, electrical engineers, of Hustlergate, Bradford, and Mr. E. Musgrave (Messrs. B. and E. Musgrave, chartered accountants, Bradford) has been appointed liquidator. The total liabilities of the company are estimated at £30,000, of which about half are secured, and the creditors are said to be evenly divided among Bradford, Halifax, and London. The assets, consisting of freehold property, plant and stock-in-trade, are expected to realise about £30,000, the same amount as the liabilities. The company, we understand, has not contracted any large amount of bad debts. It was formed a few years ago, up to which time the business was carried on by Messrs. Schmidt and Douglas. Lighting stations have been established by the company in Leeds, Bradford, and Halifax. A block of buildings illuminated by electric light in Kirkgate, Bradford, is lighted by the company. A very important factor—and apparently the principal one—in bringing about the present position of affairs is, we understand, an action taken by an adjoining property owner, complaining that the works are a nuisance. It is not expected that the claims of the trade creditors will be large, and, as regards the firm's losses, the board of directors must necessarily sustain a considerable share, as they hold fully two-thirds of the undertaking. The petition for liquidation was presented by a small creditor, and the directors, after fully considering the state of affairs, decided that their more prudent course would be not to oppose the petition. The firm had obtained a fair amount of lighting work in Halifax, and this would probably have been largely extended in a very short time if certain conditions imposed by the Corporation could be modified.—*Glasgow Herald.*

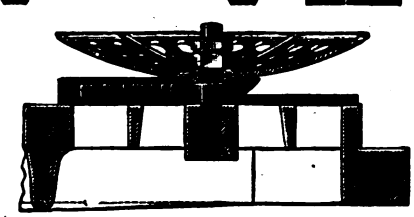
NOTICE OF REMOVAL.—The Telegraph Manufacturing Company, Limited, give notice that after September 1st their London office will be removed from 29, Queen-street, E.C., to Room 524, No. 11, Queen Victoria-street, E.C. Their head office and works remain at Helsby, near Warrington.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended August 23, 1889, amounted to £4,465.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended August 23, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,303.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 590.—Vol. XXIII. FRIDAY, SEPTEMBER 6, 1889. Price Fourpence.

NOTES.

From an electrical standpoint it seems at present scarcely probable that the meeting of the British Association, which commences next week, will prove to be quite so interesting or important as that of last year. At Bath, in addition to a highly-remarkable series of Papers and discussions in Section A, we had at least five events of special interest to physicists generally—the Presidential Address of Sir Frederick Bramwell, the address of Prof. Fitzgerald as President of Section A, that of Mr. W. H. Preece as President of Section G, Prof. Ayrton's evening lecture, and last, though by no means least, the memorable discussion on Lightning Conductors. This year, under the presidency of Prof. Fowler, the Biologists will naturally occupy a leading position, and we understand that the meeting is being looked forward to with the highest interest by all workers in this great department of Science. The address of Capt. Abney, as President of Section A, will be devoted to Photography, and that of Mr. William Anderson to the Molecular Structure of Matter, chiefly with reference to the manufacture of steel. Meanwhile the only special arrangement which is likely to be made in connection with Section A—and even this has not yet been definitely concluded—is one for holding a joint meeting with Section C (Geological), in order to hear Prof. Rücker discourse on his and Prof. Thorpe's "Magnetic Survey of the British Isles." This will doubtless prove an attractive event for the members of both Sections, and although it will necessarily be devoid of that element of controversial excitement which characterised the joint discussion of last year, it may conceivably prove even more conducive to the extension of accurate knowledge.

With regard to the Papers on electrical subjects, which have been set down for Sections A and G, we are able to give a more complete account than any which has yet appeared, although in all probability the list will be still further extended between now and Wednesday next. In Section A, Prof. Ewing discourses "On the Magnetic Viscosity in Iron," and also "On Hysteresis in the Relation of Strain to Stress;" Mr. W. H. Preece has a Paper "On the Heating Effects of Alternate Currents upon Conduction of Different Metals;" Prof. S. P. Thompson has two Papers, one "On Sparkless Electro-Magnets," and one "On a Phenomenon in Electro-Chemical Solution of Metals;" Prof. Oliver Lodge reads a Paper "On the Failure of Metal Sheets to Screen off the Electrostatic Effect of a Moving Charge;" Prof. James Blyth has "A New Form of Current-Weigher;" Prof. Schuster has a short Note "On the Discharge of Electricity through Gases;" Prof. H. Stroud reads a Paper "On the E.M.F. Produced by Abrupt Variation of Temperature at the Point of Contact of two Portions of the same Metal;" Drs. J. H. Gladstone and J. Perkins have a Paper "On the Correspondence between the Molecular Refraction, Dispersing, and Magnetic Rotation of Carbon Compounds;" Mr. J. Swinburne, either here or in Section G, will read a Paper "On the Design of Transformers." Finally, Prof. W. F. Barrett will read the Report of the Committee "On the Magnetisation of Iron."

In addition to the above programme we may confidently anticipate one or more electrical Papers, both from Sir William Thomson and from Lord Rayleigh, although the subjects have not yet been announced. We may also hope to hear, either from Dr. Lodge or from Mr. Glazebrook, some results of an important character, which they have recently worked out together in the Cavendish Laboratory. There will also be one or two exhibits. Mr. J. Edmundson will show a New Electric Current Meter, and Mr. Murday an Apparatus for Reading Indications of Distant Meteorological Instruments.

Turning to Section G, we find that the electrical features of the programme are at present somewhat of the briefest, and although the Papers set down, if we may judge from the titles, should be by no means devoid of interest, yet (as, indeed, is usually the case in Section G) there is little to be looked for in the way of absolute novelty. Mr. W. Webster will read a Paper "On the Electrical Treatment of Sewage;" Mr. J. Swinburne one "On Dynamos," and Mr. E. C. Manville one "On the Northfleet Electric Tramway." Mr. Killingworth Hedges will also discourse "On the Distribution of Electricity by Underground Mains," Mr. W. H. Preece has promised a Paper on a subject not yet communicated, and Prof. Forbes may possibly have something to say on electric launches.

The Special Committee of the Board of Electrical Control of the City of New York which was appointed in connection with the recent explosions in the electrical subways has now presented its report. The Committee is of opinion that in every case the explosions have been due to the presence of coal gas, and where no obvious means of ignition existed upon the spot it is suggested that the actual point of ignition may have been at some distance and that the flame was carried backwards along

Digitized by Google

the subway. With regard to the available means of obviating this serious difficulty, it appears that the engineers of the Subway Construction Company have found it absolutely impossible to make their ducts air-tight, and the only successful method of ventilation which has yet been attempted consists in maintaining an air pressure throughout the system. This device not only ensures ventilation but excludes the gas which would otherwise leak into the tubes. The Committee is of opinion that the responsibility rests entirely with the gas companies, and call upon them to make their service pipes air-tight. For our own part, whilst fully agreeing with these recommendations, we still feel it to be a little hard upon the gas companies, who are called on to do what the engineers of the subways profess themselves absolutely incapable of accomplishing. Meanwhile have we any grounds for believing that the London gas mains are in any better condition? If not, how are similarly unpleasant results to be obviated in this country?

Our New York correspondent furnishes us with a very interesting account of the proceedings at the annual Convention of the Edison Illuminating Companies which has just been held at Niagara Falls. It is significant to learn that the Edison General Electric Company has at length fully recognised the imperative necessity for some method of distribution capable of extension over a greater radius than that of the existing three-wire system. This question has for some time past led to considerable complaint and uneasiness amongst the local Edison companies, who are, of course, quite unable to compete with the alternate-current transformer for long-distance lighting, and who have frequently had to sit idly by whilst their competitors have swept the adjacent districts. The representatives of these companies, therefore, received with gratification the announcement that the General Company were in a position to supply continuous-current transformers for use in sub-stations; these machines will be wound for 1,000 to 1,200 volts on the primary circuit, and the largest sizes would have an output of 640 amperes on the secondary. It has been known for a long while past that Edison was anxious to develope the continuous-current transformer, but the fact that his machine is immediately ready for the market is somewhat of a surprise.

It is, however, still more surprising to learn (according to the New York *Electrical World*), that the Edison Company has so far "climbed down" that it is now actually willing to supply on demand an alternate-current transformer service. The speech in which Mr. Jenks announced this concession is quite a curiosity in its way. We quote from the report of the *Electrical World*:—

"The admissions of the warmest friends of the alternating systems, at the recent National Convention, of the terrible danger attending their use, as exemplified by the horrible tortures which have been undergone by innocent victims, and the selection by the State of this current (of the standard of 1,000 volt-potential) as an embodiment of the most deadly force known to science for the execution of criminals, all point to a very limited application of this form of apparatus. It is especially noteworthy that the dangers attending its use will shortly influence legislation, as a matter of protection to life and property. But the demand for an alternating system being recognised, it is now proposed to offer one of the most efficient type at its actual value, as being dangerous and inefficient at best, but procurable on demand."

It will be interesting to observe whether the local companies, now that the door is thus grudgingly opened, will be chiefly influenced in their choice of plant by the success of their rivals or by the appalling terrors of the alternating system which Mr. Jenks, with so much gusto, displays.

Now that Edison has gone into the alternating business, it clearly rests with him, if he be at all careful of his reputation as Inventor *par excellence*, to give us an entirely novel and successful alternate-current motor. To doubt his ability to do so would be as heinous a crime as "to speak disrespectfully of the Equator."

In our issue of December 23rd, 1887, we described and illustrated a novel and ingenious type-printing telegraph instrument which delivered its matter in column form, instead of on the well-known tape. This apparatus was the invention of Mr. F. H. Higgins, of the Exchange Telegraph Company; it was the outcome of several years of study and experiment; and we have every reason to believe that it was absolutely the first of its kind. By a singular coincidence, however, on December 22nd, 1887 (the day before we published the description of Mr. Higgins' perfected instrument) a specification was filed by Messrs. Wright and Moore describing an instrument of the same class, and this has since been followed by later patents covering various improvements on the original design. We draw attention to these facts for the reason that there now lies before us the prospectus of the "Column Printing Telegraph Syndicate (Limited)," whose avowed object is to raise the modest capital of £5,000 in order to enable it to enter upon litigation with the Exchange Telegraph Company with a view to test the validity of their patents. Apart from the somewhat questionable character of this proceeding, there are several statements in the prospectus which, to say the least, seem to require elucidation. What, for instance, in view of the facts just stated, are we to understand by the allegation that Messrs. Wright and Moore's instrument "accomplishes electrically a result which hitherto it has only been possible to achieve mechanically by means of the type-writer?" As to the probable result of the threatened litigation we are not called upon to express an opinion, though we may remark that the unquestionable priority of Mr. Higgins' patent, and the careful drawing of the claims, would seem to render its invalidation a matter of some considerable difficulty.

The negotiations between the French Government and the Telephone Company for the transfer of the property of the latter not having been brought to a satisfactory issue, the Government took possession of the service, on Sunday last, *manu militari*. At ten o'clock twelve State engineers, each attended by a police commissary, took over the twelve central offices of the Telephone Company, each and every one of whose officers in charge protested against what they termed a confiscation, declaring they submitted only to main force. By special permission of

Digitized by Google

the President of the Tribunal of Commerce, twelve *huissiers* were detached to the company's offices in order to serve proper legal notices of the protest on the representatives of the Government. This writ specifies, amongst other things, that the company has not been paid the indemnity of the transfer, nor has any arrangement even fixed the amount, and, furthermore, that the offices, apart from the wires, instruments, and plant, belong to it by right of regular leases which have not been conveyed to Government. The dispute will in all probability be fought out in the Courts. The Government, we may add, have appointed their own arbitrators to assess the amount of the indemnity, and have refused to allow the company to appoint a second one on their own behalf. The desire to have the telephonic system of the company under Government control when the forthcoming general election takes place is said by the French press to be the chief reason for the extinction of the Société des Téléphones.

THE activity displayed in the Strand by the METROPOLITAN ELECTRIC SUPPLY COMPANY has caused some surprise, inasmuch as the work of laying underground mains was commenced before their Provisional Order was even so much as confirmed by Parliament, and therefore before the expiration of the month's notice to the local authorities which the Act requires. We understand, however, that this apparent precipitation was due to an arrangement with the Vestry, who were anxious to have the work done at the same time as the repaving of the Strand.

THE companies who are now at work on their mains are the METROPOLITAN ELECTRIC SUPPLY COMPANY and Messrs. GATTI, in the Strand, and the ST. JAMES' AND PALL-MALL COMPANY, in Piccadilly. The ST. JAMES' COMPANY, which, it will be remembered, is working under a License dated December, 1888, is using bare copper strip conductors, run on china insulators, in flat-shaped iron troughs. Messrs. GATTI, who, we may remark *en passant*, have so far dispensed with the formality of a Provisional Order, are running their cables in Callender-Webber conduits, the asphalte casings of which are protected from mechanical injury by thin iron sheets. The METROPOLITAN COMPANY run their high-tension cables from the Sardinia-street Station in 6in. iron pipes, positives and negatives together. With regard to the LONDON ELECTRICITY SUPPLY CORPORATION, along the lines of railway between Deptford and Charing Cross their mains have for some time been completed, and the Grosvenor Gallery machines will very shortly be relieved of a considerable portion of their load. We may take this opportunity to contradict a rumour—which seems to have attained a wide circulation—to the effect that this Company had decided to reduce their primary potential from 10,000 to 5,000 volts. The statement has no foundation in fact.

IN the concluding paragraph of the last article headed "M. Leblanc on Alternating Motors," in a recent issue, there is a curious suggestion for converting the period of an alternating current in any required ratio. The mathematical theory of this device may be left as an appropriate exercise for third-year students, but (since the article was in print) we have taken the trouble to plot out some of the curves which are given by the transformed current; the results are curious. In the case where the period is shortened, the curve of the impressed E.M.F. is much distorted. But the effect of attempting to lengthen the period is quite different, and, indeed, if our examination be sound, it would appear that M. LEBLANC is in error in supposing that it can be done at all. In fact, when the speed of the commutator is one-half that of the poles, the impressed E.M.F. takes the form of two successive half-periods, say of + sign, followed by two half-periods of − sign, and so on. It is obvious that the device can only be worked at all with multipolar connections for the field, otherwise the necessary speed of the commutator would be prohibitive at normal frequencies. In a recent conversation with Mr. SHALLENBERGER we gathered that the same end has been attained in the Westinghouse Laboratory by purely inductive methods without moving parts.

THE fact that the possession of an Electric Lighting License carries with it certain stringent obligations as well as certain privileges has scarcely dawned as yet upon the CORPORATION OF DUBLIN, otherwise they would not have wasted several hours in a wrangling discussion as to whether or not mains should be laid in certain streets of the city. The penalty of failing to do this, and to do it within a specified time, is simply the revocation of the License.

The Birmingham Exhibition.—On Saturday, 24th ult., over 10,000 persons were admitted to the Exhibition, the attendance being the largest since the opening.

The Metropolitan Electric Lighting Schemes.—The Royal Assent was given on Friday last to the Electric Lighting Provisional Orders (Nos. 2, 3, 4 and 5) Bills.

Geelong.—The office of the *Geelong Times* is now lit throughout by the electric light. The installation was carried out by Messrs. A. U. Alcock and Co., of Melbourne.

The Annual Meeting of the Iron and Steel Institute.—The meeting of the Iron and Steel Institute takes place in Paris on the 24th inst., and a large attendance of members is expected.

The Vevey-Chillon Electric Railway.—During the engineers' *fête* at Vevey, which took place at the beginning of August, the Vevey-Chillon Electric Railway carried over 50,000 passengers.

Baroda.—The installation at the Gaekwar of Baroda's new palace was recently inaugurated. Several members of the Bombay Corporation were present at the invitation of Messrs. Siemens Brothers.

Newcastle (New South Wales).—The Secretary of Public Works states that it is the intention of the Government to light the wharves of Newcastle by electricity, and tenders will shortly be called for.

Catalogue of Engineers' Stores.—We have received from Messrs. W. H. Willcox and Co. their useful catalogue of engineers' stores. This firm manufactures a special oil for gas engines, which has met with considerable favour.

University College, Bristol.—The 1889-90 Session of this College begins on October 9th. The course of electrical engineering includes laboratory work and dynamo testing. Further particulars will be found in our advertisement columns.

Telephony at Porto Rico.—Tenders will be received up to the 30th September, 1889, at the Ministry of the Colonies, Madrid, from persons willing to contract for the installation and working for 20 years of the telephonic service of the city of Porto Rico.

Digitized by Google

Electric Railway Plant for Russia.—An order for the whole of the material for some electric railways to be laid along the courses of certain rivers of Northern Russia, which are frozen during six or seven months of the year, has been secured by a Belgian firm.

The Electric Light at the British Museum.—Preparations for the installation of the electric light in the various parts of the British Museum not at present provided with it are rapidly progressing. It is anticipated that when the main collections are illuminated a large increase of popular attendance will be secured.

The Electrical Exhibition at St. John's.—At the opening of this exhibition a cannon was fired by means of an electrical current from Vancouver, over 3,000 miles distant, and a small paper entitled the *Electric Era* was set up and published two editions daily in the exhibition building, the press being run by an electric motor.

Competitions for 1890.—The Société d'Encouragement has recently published the programme of the competitions for the year 1890. Amongst the prizes is one of 2,000fr. for the best domestic motor, to work by itself or in connection with a central station; and one of 3,000fr. for a method of long-distance transmission of energy.

Catalogue of Messrs. Appleton, Burbey and Williamson.—This is a well illustrated little catalogue containing full particulars of the numerous varieties of switches, switchboards, fuses, and fuseboards made by this firm. Messrs. Appleton, Burbey and Williamson also make a speciality of acid-proof linings for battery boxes.

Tenders Wanted.—The Municipal Council of Sydney, New South Wales, are advertising for tenders for lighting the streets, &c., by electricity. Further particulars will be found in our advertisement column, and all information can be obtained at the offices of the Agent-General for New South Wales, 9, Victoria-street, Westminster, S.W.

The Proposed Pacific Cable.—The Committee appointed recently by the San Francisco Chamber of Commerce to investigate the feasibility of laying an ocean telegraph cable from that port to Australia has reported in favour of the project, and estimates the cost of a cable line to New Zealand by way of Honolulu and Tutuila at £2,000,000.

Bradford.—The arrangements for the supply of electric light in Bradford are now practically complete. The engines have been thoroughly tested, and all the apparatus, with the exception of some minor fittings at the generating station in Bolton-road, is ready for use. The inauguration of the station will take place about the middle of this month.

An Electrical Prize.—The committee charged with examining the papers sent in in connection with the prize of 25,000fr offered last year by the King of the Belgians for the best work concerning industrial applications of electricity, has just been nominated. It is composed of Sir William Thomson and MM. Montefiore, Cornu, Roïti, Kittler, Gérard, and Ponthière.

Edinburgh and the British Association.—It has been resolved by the Town Council of Edinburgh to request the governing body of the British Association to hold next year's meeting or that of 1891 in that city. As may be remembered, the meeting of the Association in 1871 was held in Edinburgh, on which occasion Sir William Thomson was the president.

Aberdeen.—On Monday last the Town Council received a report from the Gas Committee recommending that a special meeting should be held on 7th October for the purpose of considering the propriety of applying to the Board of Trade for a Provisional Order under the Electric Lighting Acts. The recommendation of the committee was adopted.

Royal Victoria Hall.—On Saturday last this admirable institution reopened as the first People's Palace for South London. Next week there will be a dioramic entertainment relating to the Paris Exhibition, and on the first Thursday in October the ballad concerts will re-commence. The programme for the winter promises to be as full of interest and variety as ever.

The Edinburgh Exhibition.—At a meeting of the Executive Committee held last week it was announced that Sir William Thomson and Mr. W. H. Preece had been added to the list of vice-presidents. The deputation which had been sent to Paris to see Mr. Edison reported that the arrangements with Mr. Edison were nearly completed, and that they had also arranged for the transfer of a number of interesting exhibits at present on view in Paris.

Reading.—We learn that the electric light station in Reading is now supplying more lamps than the plant was originally intended to serve; and owing to the increased demand for the light by business firms, Messrs. Laing, Wharton and Down have arranged for a considerable addition to the plant. This is entirely independent of the street lighting, about which the Town Council have not taken any steps to carry out the resolution passed at their meeting in June last.

Electric Lighting at Higham Ferrers.—A correspondent informs us that a novel combined heating and lighting apparatus has been introduced into Higham Ferrers by Mr. Ambrose Marriott. This apparatus is so arranged that it can be instantly converted into a steam boiler for driving the engine and dynamo in connection with the electric light with which the works and private residence are lighted. The dynamo is a compound one of Laurence, Paris and Scott's make.

Solar Radiations and Electric Phenomena.—According to a recent Paper by M. Albert Nodon, solar radiations, if they encounter an insulated conductor (metal or carbon), communicate it to a positive charge. The magnitude of this charge increases with the intensity of the sunlight, and decreases with the hygrometric state of the air. The phenomenon ceases if clouds pass before the sun. Solar radiations, therefore, M. Nodon thinks, may be one of the causes of the electrification of clouds.

Northampton.—The prospectus of the Northampton Electric Light and Power Company has just been issued. The Directors are all well-known business men of the locality. A site has been obtained in Angel-lane for the works, and it is proposed to arrange for an immediate distribution of electricity to various parts of the town. It is intended in the first instance to put down a plant capable of supplying 14,000 lights at an estimated cost of about £19,000. From promises already received it is anticipated that 8,500 lights will be quickly taken up.

Loughborough.—At the last monthly meeting of the Town Council, the Mayor, in moving the adoption of the General Purposes Committee minutes, said, with regard to the communication from the Midland House-to-house Electricity Company, he thought they should first of all consider the company which had come, or was going to come, into their midst—the Brush Electrical Engineering Company. He thought he was only speaking the general feeling of the whole Council that they should give any privileges to that company if they had any to give.

Machine Driving by Electricity.—This is the title of an illustrated popular pamphlet published by the United Electrical Engineering Company. The numerous virtues and advantages of the electric motor are dwelt on at considerable length, and the special suitability of electricity for mines, pleasure launches, light railways, and naval work, is clearly shown. The claims of the telpherage system are also succinctly set forth. Pamphlets of this description should go a long way towards familiarising the public with the idea of utilising electricity as a motive power.

Price List of Electric Light Leads.—The price list of electric light cables and wires issued by the India-Rubber, Gutta-Percha and Telegraph Works is an excellent publication, both as regards arrangement and typography. The various cables are clearly grouped together according to the nature and degree of their insulation, and in separate tables are given full particulars respecting the diameter, weight and resistance of the different sizes of conductors. The cables made by this firm are all tested at a pressure of 450 volts after 24 hours' immersion in water at 60°F., so that the insulation may be relied upon.

The Dynamos on Board H.M.S. "Hercules."—The *Standard* correspondent on board the "Hercules," writing of the occurrences in the manœuvres, says:—"A little later the dynamos

Digitized by Google

from the search lights collapsed. If this had happened half an hour earlier, it might possibly have meant the sinking of the ship. I find that this mishap occurred in exactly the same way last year, and that it is due to the flimsy manner in which these machines are fastened to the deck. It would be better, I should think, not to fit appliances of this kind at all to old vessels, if they are liable to fail at any critical moment."

Sales by Auction.—Wednesday, September 18th, has been fixed for the sale, by Messrs. Wheatley Kirk, Price and Goulty, of the contents of Crown Works, Hackney, N.E. The same firm announce the sale, on the 24th September, of a large assortment of high-class machine tools and engines, at St. George's-circus, Borough-road, London, S.E. Mr. Scamell announces the sale, on the 17th inst., at 47, Holborn-viaduct, E.C., of a large quantity of electroliers and other fittings, being the London stock of Winfield's (Limited). Further particulars of Messrs. Wheatley Kirk's sales will be found in our advertisement columns.

Norwich.—At the last meeting of the Town Council, Mr. Squirrell moved that it be an instruction to the Electric Lighting Committee to inquire whether the fall of water at the New Mills could be utilised for the purpose of lighting the streets or any part thereof, and if so, to what extent, and what it would cost to carry on such work. He said the New Mills were now tenantless, and he believed the Water Works Company were willing to give up their lease of them to the city for a comparatively small amount. The opportunity had arisen for acquiring the mills, and if they were of any use for the production of electric light for the open spaces of Norwich, it ought not to be neglected. The motion was carried.

Belfast.—At the monthly meeting of the Corporation, on Monday last, the Gas Committee, in an appendix to their report, stated that they were of opinion that the time had arrived when the Council should obtain powers to supply electric light within the city, and they recommended that they should be authorised to apply for a Provisional Order for that purpose. The Mayor said the action of the Gas Committee had been forced upon them by recent applications for permission to erect plant in the city on the part of two or three English electric lighting companies. It was evidently undesirable that they should be allowed to anticipate the Corporation in a matter of that kind. At the same time, he did not think there was any cause for alarm with reference to their gas works, and he did not anticipate any interference with its prosperous career. The report was adopted.

The Compressed Air System in Paris.—In spite of the admirable conclusions of M. Van Rysselberghe with regard to the distribution of power by the compressed air system, this method of distribution (says *l'Electricien*) does not seem to prove very successful. The Popp Company itself is on the point of abandoning the system, and six steam-engines are at this moment being put up in the Rue Boissy d'Anglas. Perhaps the idea is to make up by this means the loss sustained up to the present in working the compressed air system, although the charge for a horse-power hour was rather high. Every horse-power hour furnished by the motor required three cubic metres of air at 1½ centimes the cubic metre; and when we add that the indications of the metre were multiplied by a certain factor (3, 12, or 13, according to circumstances) we get an approximate idea of what the cost of this so much vaunted compressed air really was. *Sic transit gloria* . . . of compressed air.

The Recent Thunderstorms.—There was a storm of considerable severity on Monday and Tuesday, chiefly in the home counties, doing great damage to property. At Hayford the lightning struck the silk-printing works of Messrs. D. Evans and Co.; the buildings caught fire, and damage to the extent of £10,000 was done. Some old cottages in the London-road, at Crayford, were struck, as well as several large elms, large portions of them being torn off and the trees split in all directions. At Northumberland Heath, the Builders' Arms was struck by lightning, the chimney-stack knocked down, and the roof damaged. Sheerness and the Isle of Sheppey were visited by a storm which lasted four hours, the vivid flashes of lightning illuminating the country for miles round. The house of Mrs. Walford, at Seal, Chart, was struck by lightning and completely burned out, the inmates having a narrow escape. It is stated that the damage done will not be less than £3,000. A very heavy thunderstorm broke over Dover early on Tuesday morning. Two vessels lying in the harbour and another in the bay had their masts struck and splintered by lightning. The storm was also severely felt at Deal, and a considerable number of telephone wires were damaged. Several sheep at Sutton Valence were killed by the lightning. Ford Croft, the residence of Mr. Thomas Plummer, Orpington, was struck by lightning, and completely wrecked. Several buildings near Faversham were struck by lightning. At Way-street a farm roof was partly stripped. At Graveney a cottage chimney was demolished. Some stables at Shepherd's-hill Farm, Sheldwich, and at Shottenden, were struck and partly unroofed, as was a farm-house near Whitstable. The storm raged over a great part of Essex throughout the night. At Brentwood some farm buildings near the town were struck by lightning and set on fire. At Rochford Hall, the residence of Mr. C. Tahor, some outbuildings were struck by lightning and ignited. Four farmsteads were fired by lightning in the neighbourhood of Braintree, great damage being done in every case. Some fine trees at Audley End and Stansted Park were struck by lightning, and a stack was set on fire at Sutton. During Monday night a heavy thunderstorm broke over Mid-Northamptonshire. At Old Duston, two miles from Northampton, a house was struck and partially destroyed. During a severe thunderstorm at Tralee, on Tuesday morning, a young man was killed by lightning.

Dublin.—At the meeting of the Corporation on Monday last Mr. Robinson, C.E, Chairman of the special committee on electric lighting, moved the adoption of a report of that committee recommending that application be made for sanction to the borrowing of £50,000 to carry the scheme into effect, and also that the committee be empowered to acquire a site other than Island Bridge. The report stated that the committee proposed to apply the system of illumination, in the first instance, in the lighting of the streets and premises from Nelson's Pillar to St. Stephen's-green, and through Dame-street, Parliament-street, Grattan Bridge, Mary-street, and Henry-street. Very valuable information had been received by the committee from other towns, but before finally deciding on the plan and estimates, a sub-committee, accompanied by the Town Clerk and the Borough Surveyor, visited various installations in which success appeared to have been obtained. Mr. Robinson urged the importance and value of electric lighting, and pointed out the advantage it would be to have the station down at Sir John Rogerson's quay, for they would there have coal at their doors, and they could avail themselves of the new system by which sewage was disposed of by the aid of electricity. They would be saved the enormous expense of sending out the sewage of Dublin to the Nose of Howth. Mr. Gill opposed the adoption of the report, because he believed that electric lighting would result in a loss to the city. —Mr. J. B. Healy did not think that such important thoroughfares as Westmoreland-street, Grafton-street, Dame-street, and other important thoroughfares in the city of Dublin should be left as they were as regarded lighting while it was in their power to adopt a much more improved system. The people of Dublin were in favour of electric lighting.—Alderman Meagher pointed out that if the Corporation did not undertake the electric lighting of Dublin, private companies were ready and anxious to step in and derive the profits to which the citizens were entitled.—The Lord Mayor said if the Corporation of Dublin waited in taking steps in this matter the ground would be occupied by somebody else. Of course there would be a risk, but not a great one, and there might be a loss for a time. The repayment of a loan of £50,000, interest and principal, would mean a penny in the pound, while the gas bill amounts to fivepence in the pound. He believed the ratepayers of Dublin were quite willing to run the risk, and he believed they would be well advised in doing so if they only had the two objects in view, that of cheapening the gas and increasing the facilities of the undertaking of the gas works by the Corporation.—The motion was then adopted by 38 to 3 votes.

THE PARIS EXHIBITION.

The Edison Electric Company.

The Edison Company have dispensed with the usual oil-cups on their dynamos, and adopted a somewhat novel method of lubrication. It will be best understood by inspection of the sketches, Figs. 1 and 2. The armature spindle, S, runs in ball bearings, of which one is shown at B, Fig. 1, in elevation. This rests on soft metal and has a slight amount of play for adjustment. The supports, shown in section with the cover removed, are made to contain oil, OO, which is continually poured over the shaft by the following simple contrivance:—A groove is cut near each end of the bearing, and the upper half is entirely cut away down to the shaft. A light copper ring, C, of V-shaped section, is slipped over each end and dropped on

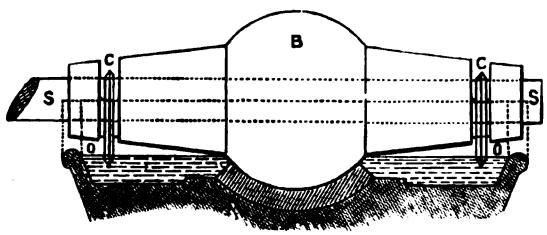

Fig. 1

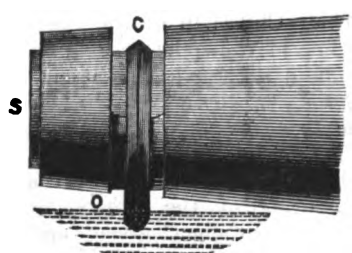

Fig. 2.

to the shaft. As the latter revolves the rings roll round on it, gathering oil as they do so, and pouring it over the shaft. The arrangement has had a good test during the past few months in the Palais des Machines, where dust is plentiful, but the machines run easily for six weeks or more without fresh oil or further attention.

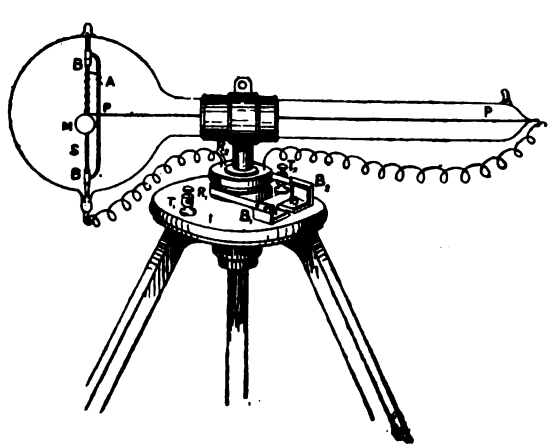

Fig. 3.—Edison Dead-Beat Mirror Galvanometer.

Most of the apparatus and instruments exhibited by this company are too well known to need detailed description, but among the physical apparatus is a dead-beat mirror galvanometer, the general construction of which will be understood from Fig. 3.

It does not seem to have been made in large numbers, but has been used considerably in Mr. Edison's laboratory since 1879. It works by means of a fine platinum silver wire, which expands when heated by the current. This wire, PP, is fixed at one end and wound round a small spindle, S, at the other; it is then passed through a small hole in S and attached to the metal support A, so that it acts like a spring and controls the action. The mirror M is attached to the spindle S, which moves in light bearings, BB. These parts are all enclosed in a glass receiver like a long-necked incandescent lamp, and the air is exhausted. The receiver is then fixed into a holder so constructed as to allow of its being turned round for adjustment, and the whole is mounted on an insulating table, I, fixed to a brass tripod with a levelling screw to each leg. A current on entering at one of the terminals T_1 would pass to the brush B_1, with which it is in contact, thence to the insulated ring R_1, and along one of the flexible connections into the receiver; it would then flow along the wire PP, and leave by the other flexible wire, reaching the upper insulated ring R_2, thence to the brush B_2 and terminal T_2. We need scarcely add that its "figure of merit" is hardly comparable with that of a Thomson galvanometer; it is, in fact, only intended for use with heavy currents. It could, however, be employed for alternating currents, and would possess many of the advantages with which we are familiar in the Cardew voltmeter.

REVIEWS.

Communications faites a la Societe Francaise de Physique et de la Societe Internationale des Electriciens, par Albert Bandsept; Articles extraits de diverse revues scientifique sur les Accumulateurs Electriques. (Cie. Imprimerie Belge, Bruxelles.)

This little pamphlet, as its lengthy title indicates, is a collection of Papers relating to secondary batteries, some by M. Albert Bandsept, civil engineer, of Brussels, others extracted from "L'Année Électrique," "Bulletin Technologique Mensuel," &c.

The articles which will justly attract the most attention are those which refer to M. Bandsept's own work in the improvement of the secondary battery. In his researches he devoted special attention to the physical influences which are manifested during the discharge. He endeavoured to determine the particular kind of molecular structure which best favours the maximum amount of electro-chemical action. The improved plates introduced by M. Bandsept are very highly spoken of, and the results of his experiments also seem to afford a novel solution of certain problems referring to the depolarisation of primary cells. It will be remembered that M. Bandsept first reduces the lead to a condition of the finest attainable subdivision, and then again compresses the metal into a solid plate, thus obtaining a material which, whilst apparently homogeneous, is in reality more or less of a porous nature.

The relative advantages of the various modifications of the original Planté battery are discussed and compared, and in the same Paper are diagrams showing sections of the plates used in the Faure-Sellon-Volckmar, the Somzée and Gadot systems.

Perhaps the most interesting article, from a strictly scientific point of view, is that in which the theory of electrolysis is carefully discussed, and this is illustrated with some ingenious and instructive diagrams, showing the molecular movements and changes which the author supposes to occur during the various stages of the process.

With regard to the capacity of accumulators it has often been stated that whatever may be the system employed the capacity per given weight is practically the same. Hence arises the question whether there is any use in trying to improve in this direction. The above statement is criticised by M. Bandsept, and the question seriously examined.

"Accumulators must be considered and compared not merely from the point of view of their absolute capacity, but in reference to their relative power for doing work in a given time."

M. Bandsept considers that there is every good reason for continuing to prosecute research on the accumulator in order to raise its power-value. He points out and enlarges upon the difficulties which are in the way, gives reasons why so many

Digitized by Google

have failed, and indicates very clearly the direction in which he believes the solution of the problem will ultimately be found.

Apart from the special interest attached to a description of M. Bandsept's own discoveries, these Papers form a valuable contribution to our knowledge of secondary batteries, and may be thoroughly recommended to those electricians who make a special study of this subject.

THE MODERN THEORY OF LIGHT.*

BY PROF. OLIVER LODGE.

To persons occupied in other branches of learning, and not directly engaged in the study of physical science, some rumour must probably have travelled of the stir and activity manifest at the present time among the votaries of that department of knowledge.

It may serve a useful purpose if I try and explain to outsiders what this stir is mainly about, and why it exists. There is a proximate and there is an ultimate cause. The proximate cause is certain experiments exhibiting in a marked and easily recognisable way the already theoretically predicted connection between electricity and light. The ultimate cause is that we begin to feel inklings and foretastes of theories, wider than that of gravitation, more fundamental than any theories which have yet been advanced; theories which, if successfully worked out will carry the banner of physical science far into the dark continent of metaphysics, and will illuminate with a clear philosophy much that is at present only dimly guessed. More explicitly, we begin to perceive chinks of insight into the natures of electricity, of ether, of elasticity, and even of matter itself. We begin to have a kinetic theory of the physical universe.

We are living, not in a Newtonian, but at the beginning of a perhaps still greater Thomsonian era. Greater, not because any one man is probably greater than Newton,†, but because of the stupendousness of the problems now waiting to be solved. There are a dozen men of great magnitude, either now living or but recently deceased, to whom what we now know towards these generalisations is in some measure due, and the epoch of complete development may hardly be seen by those now alive. It is proverbially rash to attempt prediction, but it seems to me that it may well take a period of fifty years for these great strides to be fully accomplished. If it does, and if progress goes on at anything like its present rate, the aspect of physical science bequeathed to the latter half of the twentieth century will indeed excite admiration, and, when the populace are sufficiently educated to appreciate it, will form a worthy theme for poetry, for oratorios, and for great works of art.

To attempt to give any idea of the drift of progress in all the directions which I have hastily mentioned, to attempt to explain the beginnings of the theories of elasticity and of matter, would take too long, and might only result in confusion. I will limit myself chiefly to giving some notion of what we have gained in knowledge concerning electricity, ether, and light. Even that is far too much; I find I must confine myself principally to light, and only treat of the others as incidental to that.

For now well-nigh a century we have had a wave-theory of light; and a wave-theory of light is quite certainly true. It is directly demonstrable that light consists of waves of some kind or other, and that these waves travel at a certain well-known velocity, seven times the circumference of the earth per second, taking eight minutes on the journey from the sun to the earth. This propagation in time of an undulatory disturbance necessarily involves a medium. If waves setting out from the sun exist in space eight minutes before striking our eyes, there must necessarily be in space some medium in which they exist and which conveys them. Waves we cannot have unless they be waves in something.

No ordinary medium is competent to transmit waves at anything like the speed of light; hence the luminiferous medium must be a special kind of substance, and it is called the ether. The *luminiferous* ether it used to be called, because the conveyance of light was all it was then known to be capable of; but now that it is known to do a variety of other things also, the qualifying adjective may be dropped.

Wave motion in ether, light certainly is; but what does one mean by the term wave? The popular notion is, I suppose, of something heaving up and down, or perhaps of something breaking on the shore in which it is possible to bathe. But if you ask a mathematician what he means by a wave, he will probably reply that the simplest wave is

$$y = a \sin (p t - n x),$$

and he might possibly refuse to give any other answer.

And in refusing to give any other answer than this, or its equivalent in ordinary words, he is entirely justified; that *is* what is meant by the term wave, and nothing less general would be all-inclusive.

Translated into ordinary English the phrase signifies "a disturbance periodic both in space and time." Anything thus doubly periodic is a wave; and all waves, whether in air as sound waves, or in ether as light waves, or on the surface of water as ocean waves, are comprehended in the definition.

What properties are essential to a medium capable of transmitting wave motion? Roughly we may say two—*elasticity* and *inertia*. Elasticity in some form, or some equivalent of it, in order to be able to store up energy and effect recoil; inertia, in order to enable the disturbed substance to overshoot the mark and oscillate beyond its place of equilibrium to and fro. Any medium possessing these two properties can transmit waves, and unless a medium possesses these properties in some form or other, or some equivalent for them, it may be said with moderate security to be incompetent to transmit waves. But if we make this latter statement one must be prepared to extend to the terms elasticity and inertia their very largest and broadest signification, so as to include any possible kind of restoring force and any possible kind of persistence of motion respectively.

These matters may be illustrated in many ways. but perhaps simple loaded lath or spring in a vice will serve well enough. Pull aside one end, and its elasticity tends to make it recoil; let it go, and its inertia causes it to overshoot its normal position; both causes together cause it to swing to and fro till its energy is exhausted. A regular series of such springs at equal intervals in space, set going at regular intervals of time one after the other, gives you at once a wave motion and appearance which the most casual observer must recognise as such. A series of pendulums will do just as well. Any wave-transmitting medium must similarlypossess some form of elasticity and of inertia.

But now proceed to ask what is this Ether which in the case of light is thus vibrating? What corresponds to the elastic displacement and recoil of the spring or pendulum? What corresponds to the inertia whereby it overshoots its mark? Do we know these properties in the ether in any other way?

The answer, given first by Clerk Maxwell, and now reiterated and insisted on by experiments performed in every important laboratory in the world, is:—

The elastic displacement corresponds to electrostatic charge (roughly speaking, to electricity).

The inertia corresponds to magnetism.

This is the basis of the modern electro-magnetic theory of light. Now let me illustrate electrically how this can be.

The old and familiar operation of charging a Leyden jar—the storing up of energy in a strained dielectric—any electrostatic charging whatever—is quite analogous to the drawing aside of our flexible spring. It is making use of the elasticity of the ether to produce a tendency to recoil. Letting go the spring is analogous to permitting a discharge of the jar—permitting the strained dielectric to recover itself, the electrostatic disturbance to subside.

In nearly all the experiments of electrostatics etherial elasticity is manifest.

Next consider inertia. How would one illustrate the fact that water, for instance, possesses inertia—the power of persisting in motion against obstacles—the power of possessing kinetic energy? The most direct way would be to take a stream of water and try suddenly to stop it. Open a water-tap freely and then suddenly shut it. The impetus or momentum of the stopped water makes itself manifest by a violent shock to the pipe, with which everybody must be familiar. The momentum of water is utilised by engineers in the "water-ram."

A precisely analogous experiment in electricity is what Faraday called "the extra current." Send a current through a coil of wire round a piece of iron, or take any other arrangement for developing powerful magnetism, and then suddenly stop the current by breaking the circuit. A violent flash occurs if the stoppage is sudden enough, a flash which means the bursting of the insulating air partition by the accumulated electro-magnetic momentum.

Briefly, we may say that nearly all electro-magnetic experiments illustrate the fact of etherial inertia.

Now return to consider what happens when a charged conductor (say a Leyden jar) is discharged. The recoil of the strained dielectric causes a current, the inertia of this current causes it to overshoot the mark, and for an instant the charge of the jar is reversed; the current now flows backwards and charges the jar up as at first; back again flows the current, and so on, charging and reversing the charge with rapid oscillations until the energy is all dissipated into heat. The operation is precisely analogous to the release of a strained spring, or to the plucking of a stretched string.

* Being the general substance of a lecture to the Ashmolean Society in the University of Oxford, on Monday, 3rd June, 1889. [Reprinted from the *Liverpool University College Magazine*.]

† Though, indeed, a century hence it may be premature to offer an opinion on such a point.

But the discharging body thus thrown into strong electrical vibration is embedded in the all-pervading ether, and we have just seen that the ether possesses the two properties requisite for the generation and transmission of waves—viz., elasticity, and inertia or density; hence, just as a tuning-fork vibrating in air excites aerial waves or sound, so a discharging Leyden jar in ether excites etherial waves or light.

Etherial waves can therefore be actually produced by direct electrical means. I discharge here a jar, and the room is for an instant filled with light. With light, I say, though you can see nothing. You can see and hear the spark indeed—but that is a mere secondary disturbance we can for the present ignore—I do not mean any secondary disturbance. I mean the true etherial waves emitted by the electric oscillation going on in the neighbourhood of this recoiling dielectric. You pull aside the prong of a tuning-fork and let it go: vibration follows and sound is produced. You charge a Leyden jar and let it discharge: vibration follows and light is xcited.

It is light just as good as any other light. It travels at the same pace, it is reflected and refracted according to the same laws; every experiment known to optics can be performed with this ethereal radiation electrically produced, and yet you cannot see it. Why not? For no fault of the light; the fault (if there be a fault), is in the eye. The retina is incompetent to respond to these vibrations—they are too slow. The vibrations set up when this large jar is discharged are from a hundred thousand to a million per second, but that is too slow for the retina. It responds only to vibrations between 4,000 billions and 7,000 billions per second. The vibrations are too quick for the ear, which responds only to vibrations between 40 and 40,000 per second. Between the highest audible and the lowest visible vibrations there has been hitherto a great gap, which these electric oscillations go far to fill up. There has been a great gap simply because we have no intermediate sense-organ to detect rates of vibration between 40,000 and 4,000,000,000,000,000 per second. It was, therefore, an unexplored territory. Waves have been there all the time in any quantity, but we have not thought about them nor attended to them.

It happens that I have myself succeeded in getting electric oscillations so slow as to be audible. The lowest I have got at present are 125 per second, and for some way above this the sparks emit a musical note; but no one has yet succeeded in directly making electric oscillations which are visible, though indirectly everyone does it when they light a candle.

Here, however, is an electric oscillator which vibrates 300 million times a second, and emits etherial waves a yard long. The whole range of vibrations between musical tones and some thousand million per second, is now filled up.

These electro-magnetic waves have long been known on the side of theory, but interest in them has been immensely quickened by the discovery of a receiver or detector for them. The great through simple discovery by Hertz of an "electric eye," as Sir W. Thomson calls it, makes experiments on these waves for the first time easy or even possible. We have now a sort of artificial sense-organ for their appreciation—an electric arrangement which can virtually "see" these intermediate rates of vibration.

The Hertz receiver is the simplest thing in the world—nothing but a bit of wire or a pair of bits of wire adjusted so that when immersed in strong electric radiation they give minute sparks across a microscopic air gap.

The receiver I have here is adapted for the yard-long waves emitted from this small oscillator; but for the far longer waves emitted by a discharging Leyden jar an excellent receiver is a gilt wall-paper or other interrupted metallic surface. The waves falling upon the metallic surface are reflected, and in the act of reflection excite electric currents, which cause sparks. Similarly, gigantic solar waves may produce auroræ; and minute waves from a candle do electrically disturb the retina.

The smaller waves are, however, far the most interesting and the most tractable to ordinary optical experiments. From a small oscillator, which may be a couple of small cylinders kept sparking into each other end to end by an induction coil, waves are emitted on which all manner of optical experiments can be performed.

They can be reflected by plain sheets of metal, concentrated by parabolic reflectors, refracted by prisms, concentrated by lenses. I have at the College a large lens of pitch, weighing over three hundredweight, for concentrating them to a focus. They can be made to show the phenomenon of interference, and thus have their wave length accurately measured. They are stopped by all conductors and transmitted by all insulators. Metals are opaque, but even imperfect insulators such as wood or stone are strikingly transparent, and waves may be received in one room from a source in another, the door between the two being shut.

The real nature of metallic opacity and of transparency has long been clear in Maxwell's theory of light, and these electrically produced waves only illustrate and bring home the well-known facts. The experiments of Hertz are in fact the apotheosis of that theory.

Thus, then, in every way Maxwell's 1865 brilliant perception of the real nature of light is abundantly justified; and for the first time we have a true theory of light, no longer based upon analogy with sound, nor upon a hypothetical jelly or elastic solid.

Light is an electro-magnetic disturbance of the ether. Optics is a branch of electricity. Outstanding problems in optics are being rapidly solved now that we have the means of definitely exciting light with a full perception of what we are doing, and of the precise mode of its vibration.

It remains to find out how to shorten down the waves—to hurry up the vibration until the light becomes visible. Nothing is wanted but quicker modes of vibrations. Smaller oscillators must be used—very much smaller—oscillators not much bigger than molecules. In all probability—one may almost say certainly—ordinary light is the result of electric oscillation in the molecules of hot bodies, or sometimes of bodies not hot—as in the phenomenon of phosphorescence.

The direct generation of *visible* light by electric means, so soon as we have learnt how to attain the necessary frequency of vibration, will have most important practical consequences.

Speaking in this University, it is happily quite unnecessary for me to bespeak interest in a subject by any reference to possible practical applications. But any practical application of what I have dealt with this evening is apparently so far distant as to be free from any sordid gloss of competition and company promotion, and is interesting in itself as a matter of pure science.

For consider our present methods of making artificial light; they are both wasteful and ineffective.

We want a certain range of oscillation, between 7,000 and 4,000 billion vibrations per second; no other is useful to us, because no other has any effect upon our retina; but we do not know how to produce vibrations of this rate. We can produce a definite vibration of one or two hundred or thousand per second; in other words, we can excite a pure tone of definite pitch; and we can demand any desired range of such tones continuously by means of bellows and a keyboard. We can also (though the fact is less well known) excite momentarily definite etherial vibrations of some million per second, as I have explained at length; but we do not at present seem to know how to maintain this rate quite continuously. To get much faster rates of vibration than this we have to fall back upon atoms. We know how to make atoms vibrate; it is done by what we call "heating" the substance, and if we could deal with individual atoms unhampered by others, it is possible that we might get a pure and simple mode of vibration from them. It is possible, but unlikely; for atoms, even when isolated, have a multitude of modes of vibration special to themselves, of which only a few are of practical use to us, and we do not know how to excite some without also the others. However, we do not at present even deal with individual atoms; we treat them crowded together in a compact mass, so that their modes of vibration are really infinite.

We take a lump of matter, say a carbon filament or a piece of quicklime, and by raising its temperature we impress upon its atoms higher and higher modes of vibration, not transmuting the lower into the higher, but superposing the higher upon the lower, until at length we get such rates of vibration as our retina is constructed for, and we are satisfied. But how wasteful and indirect and empirical is the process. We want a small range of rapid vibrations, and we know no better than to make the whole series leading up to them. It is as though, in order to sound some little shrill octave of pipes in an organ, we are obliged to depress every key and every pedal, and to blow a young hurricane.

I have purposely selected as examples the more perfect methods of obtaining artificial light, wherein the waste radiation is only useless, and not noxious. But the old-fashioned plan was cruder even than this; it consisted simply in setting something burning; whereby not the fuel but the air was consumed, whereby also a most powerful radiation was produced, in the waste waves of which we were content to sit stewing, for the sake of the minute—almost infinitesimal—fraction of it which enabled us to see.

Everyone knows now, however, that combustion is not a pleasant or healthy mode of obtaining light; but everybody does not realise that neither is incandescence a satisfactory and unwasteful method which is likely to be practised for more than a few decades, or perhaps a century.

Look at the furnaces and boilers of a great steam-engine driving a group of dynamos, and estimate the energy expended; and then look at the incandescent filaments of the lamps excited by them, and estimate how much of their radiated energy is of real service to the eye. It will be as the energy of a pitch-pipe to an entire orchestra.

It is not too much to say that a boy turning a handle could, if his energy were properly directed, produce quite as much real light as is produced by all this mass of mechanism and consumption of material. There might, perhaps, be something contrary to the laws of nature in thus hoping to get and utilise some specific kind of radiation without the rest, but Lord Rayleigh

Digitized by Google

has shown in a short communication to the British Association at York that it is not so, and that therefore we have a right to try to do it.

We do not yet know how, it is true, but it is one of the things we have got to learn.

Anyone looking at a common glow-worm must be struck with the fact that not by ordinary combustion, nor yet on the steam-engine and dynamo principle, is that easy light produced. Very little waste radiation is there from phosphorescent things in general. Light of the kind able to affect the retina is directly emitted; and for this, for even a large supply of this, a modicum of energy suffices.

Solar radiation consists of waves of all sizes, it is true; but then solar radiation has innumerable things to do besides making things visible. The whole of its energy is useful. In artificial lighting nothing but light is desired; when heat is wanted it is best obtained separately by combustion. And so soon as we clearly recognise that light is an electrical vibration, so soon shall we begin to beat about for some mode of exciting and maintaining an electrical vibration of any required degree of rapidity. When this has been accomplished, the problem of artificial lighting will have been solved.

ON SOME MECHANICAL DETAILS OF ELECTRICAL MACHINERY.*

BY A. J. SHAW.

In the practical application of electrical machinery to heavy work, more failures have resulted from lack of sufficient attention to mechanical details of construction than from any other single cause, if not more than from all other causes combined. Many electricians have never learned to look upon electrical machinery as anything more than laboratory apparatus. This may be due to the fact that they are scientific experimenters and not mechanics. This is not universally the case, however, for that some are fine mechanical as well as electrical engineers is shown by the character of their work.

In designing dynamos and motors for heavy duty a liberal margin should always be allowed for overloading, abuse, and neglect, not only in the electrical portion of the apparatus, but in all the mechanical details as well.

Brushholders in which the brushes are held in place by small nurled head-set screws; binding posts and flimsy connectors in or to which still more unsubstantial screws are expected to secure large conductors, are things which one would hardly expect to find on dynamos and motors from reputed first-class makers; but one does find them, nevertheless.

Screws for connections should have square or hexagonal heads in all cases when possible, and set and binding post screws should have heads of the same shape. Screws requiring too frequent adjustment to make the use of a wrench undesirable should have liberal "wing" heads, or heads with cross pins. Nurled heads are an abomination, and should never be used on heavy machinery under any circumstances.

Screws to which connections are made by twisting the wire around them should be especially substantial, and should in all cases be provided with liberal washers.

In many engineering establishments it is one of the unwritten rules never to use a set screw less than, say, $\frac{3}{8}$, or a bolt less than $\frac{1}{2}$ or $\frac{5}{8}$ of an inch in diameter, except by "special dispensation." Even when the nominal load on the bolt is such that it might be carried by one that is much smaller, it has been found the only safe way to allow a liberal margin for contingencies—such, for instance, as a burly labourer at the end of a monkey wrench. Similar rules, modified as to the sizes of the bolts and screws to be used, should apply to heavy electrical work.

The "factor of safety" has been called a "factor of ignorance." It should sometimes be based on the ignorance of the user.

A motor, designed specially for very heavy duty in a situation where anything more than the most ordinary care was not to be expected, was provided with connectors having $\frac{3}{16}$in. slot-headed brass screws for securing conductors of No. 4 A.W.G. wire. It is, perhaps, superfluous to state that some of these screwed themselves off instead of in, and had to be replaced with screws of iron.

Not only are liberally-proportioned screws less likely to get broken, twisted off, or otherwise crippled, than the imitation fastenings often furnished, but better contacts, and consequently less trouble from heating, as well as a higher electrical efficiency, are obtainable, as the larger screws can be set down hard enough to exert a reasonable degree of pressure.

There is a motor in the market, the brush-holders of which are pitted with brass screws about $\frac{3}{16}$ of an inch in diameter, with nurled heads about $\frac{5}{8}$ of an inch in diameter. One of these screws is supposed to be sufficient to clamp the brush securely in place. It did hold for a short time, when the brush slipped, was readjusted, and soon slipped again. This time a persuader was applied, in the shape of a pair of pliers, and the brush did not slip again.

When it became necessary to readjust the brush on account of wear, the set screw seemed disinclined to let go. On inspection it was found that the part of the screw between the point and the yoke, into which it was tapped, was somewhat larger than when made. The screw was finally gotten out, but the thread in the holder was ruined. It was then tapped $\frac{5}{16}$, and fitted with an ordinary case-hardened, square head, set screw. This is not quite as handsome, from the apparatus makers' standpoint, as the original arrangement, but it is much more satisfactory to the man who runs the motor.

Set screws of brass, especially of the soft yellow brass rod commonly used, are a nuisance, as the points invariably upset as soon as any attempt is made to screw them up tight. There are situations in which iron or steel set screws are inadmissible, but they can be used in nine places out of ten in which those of brass are considered the only orthodox thing. Some makers of fittings are using them quite extensively, and it is certainly a start in the right direction.

The brass yokes which carry the armature bearings are sometimes very weak. This state of things arises, no doubt, from a laudable desire on the part of the maker to economise in the weight of brass, although in many cases it is due simply to bad design, as there is sufficient metal in the yokes to make them amply rigid, if it were properly disposed.

In motors from which the power is taken by a belt, this weakness is not always so perceptible; but when a pinion on the armature shaft is substituted for the belt pulley, the lack of strength may become only too apparent.

There is scarcely any single mechanical detail in a dynamo or motor in which weakness is more fatal than in the armature shaft, and yet this defect is not uncommon. On account of the high speed at which they run, armature shaft bearings are necessarily made very long. On this account, in order that they may not deflect in their own length, the diameter should be considerably greater than that due to the torque alone. A long bearing which springs is worse than a short one which is rigid; and a bearing which is amply large, as far as ultimate strength is concerned, may deflect very appreciably when subjected to the cross pull of the driving belt or the reaction of a small pinion.

In one case, that of a motor, the power of which was transmitted through a small pinion, as in street-car work, the bearing next to the pinion was worn very badly in a very short time, apparently from this cause alone—the weakness of the shaft. The low surface velocity of the journal due to the small diameter is very desirable, but is paid for too dearly when obtained at a sacrifice of strength. Any increase of velocity of sliding due to an enlarged diameter is partially, if not entirely, compensated for by the increase in the bearing area and the reduction of pressure per unit of surface. Switches are frequently constructed in a very unsubstantial manner, with insufficient surface and poor contacts. In a certain reversing switch, the insulating surface on which the sliding block runs, after leaving the last block of the rheostat, is of wood. This wood wears away quite rapidly, and the process is hastened by the temporary arc formed between the blocks on breaking contact, and finally the wood surface has become so much lower than the rheostat blocks as to render the operation of the switch somewhat difficult.

In a switch designed to control a motor attached to machinery in a foundry, the rheostat lever was connected to the hand lever by a light bar pivoted on the points of small headless brass screws. No provision was made for preventing the loosening of these screws except the tightness of their fit in the threads. Owing to a change in the arrangement of the machinery, this switch was not used. How long it would have remained in working order under the conditions necessarily obtaining in a foundry ought not to be difficult to predict.

Sliding contacts can hardly be made too large; it is very easy to make them too small. On this account sliding contacts are preferable to rolling contacts, wherever it is possible to use them. Rolling contacts conveying heavy currents are troublesome things, as everyone who has tried them can testify. This does not apply to the higher voltages and smaller quantities usual in street-car service.

Not all electrical machinery is open to the criticisms made in the preceding Paper, as there is much which is fully up to the standard of the best mechanical work in design and construction.

* From the *American Gas Light Journal.*

Formosa.—According to the British Consul at Tamsui, the new city of Tai-pei Fu, the capital of the Island of Formosa, is lighted by electricity, the apparatus being attended to by native officials.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The DIRECTORY was established in 1883, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

"THE ELECTRICAL WORLD" OF NEW YORK.

Arrangements have been made by which "THE ELECTRICAL WORLD" OF NEW YORK *can be obtained from* "THE ELECTRICIAN" *Office, 1, Salisbury-court, Fleet-street, London, E.C.*

The Rate of Subscription (payable in advance), is **£1 1s. 0d.** *per annum.*

Single Copies of "THE ELECTRICAL WORLD" *can also be obtained,* **price 6d. each; post free, 7d.**

"THE ELEKTROTECHNISCHE ZEITSCHRIFT" OF BERLIN.

"THE ELECTRICIAN" COMPANY *are also Agents for* "THE ELEKTROTECHNISCHE ZEITSCHRIFT" OF BERLIN, *published Fortnightly, and copies of this well-known Electrical Journal can be obtained at the Offices of* "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, E.C.,* **price 8d., post free, 10d.** *The Annual Subscription is* **£1. 2s. 6d.** *(post free),* PAYABLE IN ADVANCE.

Subscriptions are received by this Company for all Continental and American Electrical Journals. Subscription Rates on application to "THE PUBLISHER." *Remittance must accompany order* IN ALL CASES.

THE INTERNATIONAL ELECTRICAL CONGRESS OF 1889.

Whether the International Electrical Congress of 1889 is or is not to be pronounced a success depends entirely upon what we may happen to conceive to be the precise scope and functions of an International Electrical Congress. Regarded as a means of bringing together, under conditions of the pleasantest and most interesting kind, a large contingent of workers in the electrical field of various nationality and of varying calibre, nothing could well have been more successful. The roll of the Congress extended to upwards of 600 members, the great majority being naturally of French nationality; yet the English members numbered not less than 40, and the United States was represented by some 12 or 15 well-known names. It would indeed be ungracious—even ungrateful—did we not acknowledge in the fullest sense of the word the unwearied cordiality and marked hospitality of our French *confrères*. From a social point of view the affair was, in fact, a complete success from the first day to the last.

But it must perforce be acknowledged that this is not of itself sufficient to ensure that the Congress of 1889 will live in the history of Electrical Science as an event of real importance. Nor, to be quite candid, do we at all suppose that it will do so. It will be remembered that the ostensible object for which the Congress was held was to continue the work of 1884; but it was sufficiently obvious, as we remarked at the time of the inception of the idea, that the earlier Congress had left but little material for the deliberations of its successor to which any in

Digitized by Google

ternational or any pressing degree of importance could be attributed. Some few points of secondary (or even less) importance were, indeed, left outstanding, and upon these the Congress of 1889 has now expended its collective wisdom, and has, we hasten to add, arrived, in our opinion, in each case at a completely satisfactory conclusion. This achievement was, however, somewhat the less arduous since, with but few exceptions, its *rôle* has been limited to the "legalisation" of terms which both the British Association and established usage had already sanctioned. It demanded but little courage or originality to endorse the use of the terms "watt" and "joule;" nor does the definition of such terms as "period," "frequency," "mean" and "effective" current, and "apparent resistance," involve any high order of intellectual effort. With regard to the remaining decisions some few will, however, bear further comment. The Congress has, for instance, officially decided to adopt the long-standing idea of Mr. PREECE, and to substitute the "kilo-watt" for the horse-power as the practical unit of mechanical power. We have not the slightest objection to make; on the contrary, we shall heartily welcome the day when the numeric "746" will disappear from our tables of physical constants. We only wish, however, that we could persuade ourselves that this happy event has been brought appreciably nearer by the vote of the Congress. But when the question is essentially a mechanical one, it is a far reckoning from a casual conference of Electricians to the Institution of Civil Engineers and their compeers. We none the less heartily congratulate Mr. PREECE on having made at least one step towards the goal he has long had in view, and which implies a reform at once scientifically desirable and practically useful.* Turning to the vexed question of photometry, on the proposition of M. VIOLE the one-twentieth part of the (so-called) absolute standard was adopted as the practical photometric unit; this happens to be very nearly one-tenth of a carcel, and hence it is not very different from the English standard candle. The name proposed for the new unit is the "bougie-decimal," but probably we shall hear little of it in this country. We wish the Congress could have seen its way to deal satisfactorily with the far more important question of the absolute standard itself. Possibly, however, the British Association will sooner or later be able to arrive at some conclusion upon this point which another International Congress may give itself the felicity of registering. The Congress has also adopted the recommendations of M. CROVA as to the means to be employed for determining the mean horizontal radiation of an incandescent lamp. The method consists essentially in revolving the lamp while in the photometer. The principle is doubtless sound, although the experiments shown at the meeting were not wholly successful. The "secohm" was thrown over in favour of the "quadrant"—an edict as to which the chief thing to be said would seem to be that it affords Profs. AYRTON and PERRY an excellent opportunity of displaying a loyal submission to the powers that be. The solemn recommendation that metallic circuits should be employed for telephone lines must have been adopted in a weak moment when both the dignity and the limitations of an International Congress were absent from the minds of the members present. We wonder how many Telephone Companies in any known part of the Universe will allow their action in this matter to be influenced by the opinion of the Congress? Suggestions of an even more insipid character were not wanting from the meetings of the Sections, but of these only a single specimen got as far as the General Meeting, where it also received its quietus. (We add parenthetically that we refer to the "pious opinion" of Section III.—that people using telephone call-boxes should not be allowed more than three minutes' talk for a single payment!)

Turning now to the detached papers, considered collectively, we find very little indeed to be said; the majority were decidedly below the average level of the electrical Papers in Section G of the British Association, and like the latter, they consisted for the most part either of *réchauffées* of Papers already read elsewhere or of descriptions of more or less well-known apparatus in too many cases of a more or less unimportant character. We regret to add that even the scanty contributions of the English members found no exception to this rule; Prof. S. P. THOMPSON, Prof. FORBES, and Mr. W. H. PREECE all dealt with questions upon which, however interesting or important, they had already delivered their views elsewhere. Mr. CROMPTON was, perhaps, a partial exception; we do not know that he has ever before promulgated (in public, at any rate) his "Ten Rules for the proper regulation of central station accumulators." But omitting two or three statistical clauses which are not "regulations" at all, the conviction is forced upon one that so sensible, practical, and accomplished an electrician as Mr. CROMPTON could not possibly have fathered any set of rules for the management of accumulators which could appreciably differ from these.

But after all has been said, we repeat once more the sentiment expressed at the beginning, that if we only forbear to demand too high a standard of scientific achievement, the Congress of 1889, with its attendant festivities, was an undoubted, indeed, a marked success, and personally we are sorry that there will not be another till 1892.

PARIS INTERNATIONAL ELECTRICAL CONGRESS.

(FROM OUR SPECIAL CORRESPONDENT.)

Wednesday, August 28.

On Wednesday, Section I. was again occupied with the determination of various units. M. Wuilleumier described the determination of the ohm by an electro-dynamic method due to the President, M. Lippmann. A German silver ribbon had its resistance first determined in C.G.S. units by this method, and then again in legal ohms by comparison with the standards kept in the International Bureau of Weights and Measures. The true ohm was found to be the resistance at 0° C. of a column of mercury one square millimetre in section, and 106·27 centimetres long. The method is a simple modification of that of Lorenz, the solenoid being covered with very fine wire, wound in only one layer, and the E.M.F. used being comparatively large. The approximative accuracy of the result was said to be $\frac{1}{2500}$. Mr. Preece submitted the proposal that he first made, in 1881, to substitute the kilowatt for the horse-power measure of the rate of doing work. The word watt was only proposed in 1882 by Sir William Siemens, but in 1881 Mr. Preece proposed 1,000 volt-amperes as a practical unit. A kilowatt equals 1·358 French *force-de-cheval*, and 1·3405 English horse-power. It is an erg-ten per second. Mr. Preece also proposed to establish a unit intensity of surface illumination, which he would call a "*lux*," the plural being "*luces*." The definition of the lux is the illumination produced by a lamp of one carcel on a surface one metre away from the lamp. It is nearly the same as is produced by the English "candle" at one foot distance. To make the definition exact it would need to be specified whether the light is to be radiated through vacuum or some other standard medium. The Section at this time came to no decision on either of these questions.

Section II. (Industrial Applications) was the favourite rendezvous on Wednesday, and the room was crowded up to after 12 o'clock, the several Papers calling forth much lively discussion.

* A Note read at the Congress by Mr. Preece on the subject of the kilowatt will be found on p. 456.

Digitized by Google

The first was by Mr. Crompton, who recommended a set of ten rules for the proper regulation of central-station accumulator installations. These were as follows :—

1. A battery of 54 elements should have sufficient capacity to discharge 100 amperes for 10 hours without the external voltage falling below 100.
2. The same battery should be charged by 200 amperes in five hours.
3. In case of emergency the battery should be able to furnish 500 amperes for half an hour, still maintaining the external voltage at 100—that is, 1·86 volts per element.
4. The normal efficiency should be taken to be that obtained when the battery is charged by a current of 200 amperes and the discharge is 100 amperes.
5. All the connections should be so simple that one man can take charge of six batteries.
6. The battery should be mounted with regulating apparatus, preventing the charging electromotive force from rising more than 5 per cent. above the necessary amount.
7. The connections should be so made that any of the plates or elements may be removed for repair without interruption of the charging or discharging current.
8. The insulation resistance of the battery and its connections should be at least 10,000 ohms even in damp weather.
9. Each element should be covered so to avoid the escape of acid vapours during the charge.
10. The material of the cells should be absolutely resistant to the attack of the acids.

The proposed "rules" did not seem to call forth any remarks, critical or otherwise, and the next speaker was Major-General Webber, who gave particulars of the central station of the Electrical Power Storage Company, at Chelsea,* which supplies 600 amperes at 100 volts, and feed 2,000 lamps of 30 volts. There are eight batteries of 54 accumulators. Five months' trial has shown the consumption of coal to be 5 to 7 kilogrammes per 1,000 watt-hours.

M. Drzewiëcki then expounded a new chemical theory of lead accumulators. He believes that the acid formed during the charge is $H_2Pb_2O_7$. This is decomposed during discharge, H_2O_2 being liberated, which again decomposes into water and free oxygen. The free oxygen combines with the hydrogen of the hydrate of lead, giving water and metallic lead. This theory would make the weight of the plates decrease during discharge, while the ordinary theory would make it increase.

In the discussion which followed, M. Gaston Roux defended the theory of double sulphating, and reminded the meeting that the results of some experiments, which were recently published in *l'Electricien*, showed that the lead plate absorbed 1·41 gramme of sulphuric acid per ampere-hour and the peroxide plate 2·293 gramme, which led one to believe in the existence of two new sulphates of lead. M. E. Reynier thought that the unequal quantity of acid absorbed by the two plates was probably due to a systematic error arising from the employment of a porous vase separating the two electrodes. This suggestion was, however, not entertained by M. Roux, who said that the analysis of the liquid showed an absorption of 3·7 gramme of acid per ampere-hour.

M. Reynier next read a Paper on the "Activity and the Work of Voltaic Couples." The gist of this Paper was a proposal to measure the "activity" by the velocity at which the work done by the cell could lift its own (the couple's) weight. This somewhat fanciful idea was strongly objected to by Messrs. Hospitalier and Faure, and led to a long discussion as to how the power could best be measured. M. Huber contributed a seemingly necessary reminder that the capacities of accumulators are proportional to their exposed surfaces and not to their weights. The President interposed a proposition that it would be desirable to have definite names for the two plates of a cell in an accumulator. Some members wished them to be called "red" and "white," which, whether definite or not, has not a very scientific tone about it. Another member proposed the names "cathanode" and "ancathode." Naturally, no decision was arrived at.

There was then brought forward, on behalf of Mr. Webster, an interesting description of his method of treating sewage and flood waters by letting them flow over cast-iron electrodes connected by copper leads to a dynamo.* All organic matters are precipitated under the action of the current. The method is also applicable to the purification of drinking waters.

Afterwards a dynamometer with fluid resistance was described, but it appeared to possess no particularly interesting features nor any great mechanical merit.

The third Section met in the afternoon only, but had then a most interesting discussion upon the influence of the proximity of lighting and telephonic circuits upon the good working of the latter. This discussion arose out of a Paper by Mr. Lopaz, who attributed the whole effect to leakage from the industrial lines to the earth which forms part of the telephonic circuit. He concluded that all telephonic installations should be constructed with a double-wire circuit, which conclusion was afterwards confirmed by the vote of the meeting. M. Vaschy maintained that the inductive effects due to the proximity of the wires were more important than those mentioned by M. Lopaz, and cited particular installations where the inductive effects had been measured in order to prove his proposition. MM. Palaz, Mercadier, Banneux, Pollard, Barbarat and d'Infreville continued the discussion, taking different views of the matter, and finally it was determined to recommend the universal adoption of the double-wire system, this being important whatever view of the cause of the phenomenon be taken.

In the evening a larger number of the members met at the Central Laboratory at the Place Saint Charles to witness a repetition of Herz's experiments by M. Joubert. These experiments have already been described in this journal, and it is, therefore sufficient to say that the demonstrations were perfectly successful on Wednesday evening. One particular device is, however, worth noting, and is illustrated in the adjoining

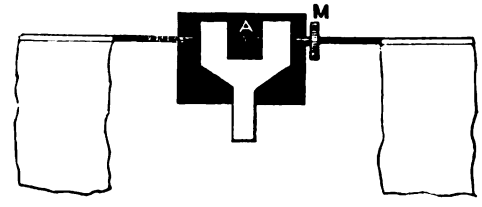

figure. In order to increase the visibility of sparks of the most minute order, Prof. Joubert employs the frame shown in the figure, and which has a piece of black cloth behind the sparking points. This frame is held in the hand, and is brought up close to the eye. The distance between the points is regulated by the screw seen on the right hand; the pieces of tin foil seen on either side may be taken of various sizes in order to act as resonators for the particular rate of oscillation then being employed.

The Units Commission met on Wednesday, and came to two resolutions regarding the joule and the watt, which will be referred to subsequently. This Section (Units and Standards) did not meet on Thursday.

Thursday, August 29.

In the Industrial Section, on Thursday morning, a very interesting Paper was read by M. R. Arnoux on the "Experimental Study of Dynamos." He pointed out that the whole character of a dynamo may be represented by a surface of which the three rectangular co-ordinates are any three of the following four quantities: the mechanical effort, the speed, the current, and the electromotive force. The first three quantities are the only ones that can be determined directly by experiment, because one cannot measure the E.M.F. generated in the armature except by calculation according to Ohm's law from the measured E.M.F. at the brushes. The equation connecting these three being found by experiment, the equation of conservation of energy combined with it gives the fourth quantity. A large number of experimental figures were given to illustrate the method proposed, but it subsequently transpired that these were not the results of original experiments, but were bor-

rowed from Silvanus Thompson's book on "Dynamo Electric Machinery."

M. J. Laffargue next read a Paper on the "Relative Economy in the Material of the Leads with Different Systems of Distribution." He showed that the use of three instead of two wires leads to an economy of from 60 to 68 per cent., while, if the current be distributed from two, three, or five centres instead of by means of an ordinary simple circuit, an economy of from 20 to 57 per cent. is obtainable. The economy of leads of varying section was also investigated, but the Paper really contained nothing new.

A Paper by M. Turrettini explained a method of minimising the variation of electromotive force in an electric installation fed by accumulators by help of two dynamos, which together act as a transformer, the one driven by the main current feeding the accumulator-battery, and the second, driven by the first, supplying at higher potential an extra current to the secondary circuit from the battery. This transformer-arrangement is automatically put in action when the E.M.F. of the secondary falls below the permissible limit. This system had been suggested by a similar hydraulic arrangement on the Rhone at Geneva, where a centrifugal pump was automatically thrown into gear when the hydraulic pressure in a certain part of this system fell below a given point. It was said that the cost both of installation and of maintenance would be reduced by the adoption of the device.

In Section III. there was distributed to the members a bulky volume, issued by the Government of the Mexican Republic, describing the progress that that country has made in electrical matters. A cursory examination of this book shows a surprising stage of advancement in Mexico, as may be judged by the fact that there are now about 5,000 miles of telephonic lines in operation. The Section was engaged most of the morning in listening to a Paper by M. Chaze, in which he explained the great advantage that would accrue from the invention of a relay-signal for submarine purposes, such as listening on shipboard in foggy weather for lighthouse signals by help of a combination of the telephone and microphone. It is already possible to make use of this combination if the operator on shipboard keeps his ears continuously to the telephonic receiver, but the utility of the system would be immensely increased by the invention of a signal apparatus which would call the listener to his post whenever there was anything to listen to. By the same system lighthouse guardsmen could obtain intimation of the passage or approach of vessels invisible on account of fog. At the present time, however, no such instrument, to his knowledge, existed. The reader of the Paper was highly complimented by Prof. Hughes, and the sitting terminated with a description of Munier's multiple printing telegraph (details of which we shall probably lay before our readers a little later), and by a discussion regarding the proper number of "tariff" minutes to be allowed for telephonic conversations on public lines.

In the afternoon visits were paid to the electric light installations at the Palais Royal and at the Opera. The machine rooms in both cases are underground, and the temperature was such as to make these visits very fatiguing to the majority of the company. However, a goodly crowd of scientists endured all these hardships in the pursuit of knowledge.

At the Palais Royal there are installed six Edison dynamos which were put down about eighteen months ago, each giving 800 amperes at 110 volts, or 88 kilowatts.

There are also two Zipernowski alternate-current machines of more recent date (having been put down this year), each supposed to give 84 (but actually giving about 80) kilowatts external to the machines. The power is supplied by two four-cylinder compound engines built by Weyher and Richmond. The steam, initially supplied at eight atmospheres pressure during daytime and ten at night, passes successively through all four cylinders; but as there is little or no expansion in the first cylinder, these are called in France triple-expansion engines. Each engine developes about 150 horse-power, the first cylinder being of 10-inch diameter and the second 15 inches. Sets of resistances are conveniently arranged for the regulation of the intensity of the magnetic fields. The whole of the fittings are compactly and well designed, but cannot be described in detail here. This interesting and very successful installation is due to the Compagnie Continentale Edison.

In 1882 the first incandescent lamp installation of the Opera was carried out by the same company. At first 2,500 lamps were mounted, but the number is now over 7,100 16-candle lamps, of which 2,000 are on the stage. The footlights have white and blue globes, the former considerably outnumbering the latter. The lamps are placed as close together as possible across the whole front of the stage. The scenic effects are produced by four rows of lamps in the battens, and each of these can be coloured independently by means of a cylindric revolving shade worked by a windlass and chains from the coulisses at the side.

In the underground workshop there is, firstly, a group of three Edison 88 kilowatt-dynamos (88 amperes × 100 volts), giving continuous-current, and driven by three compound 2-cylinder engines of the vertical inverted type, developing 150 horse-power each, with steam at seven atmospheres. The speed of the engines is 120 revolutions per minute, and that of the dynamos 350. The next group comprises five Edison continuous current machines, each giving, at 820 revolutions per minute, 400 amperes at 105 volts or 42 kilowatts. There are also two alternate-current Gramme machines for feeding Jablochkoff candles. The smaller of these, giving 12 horse-power and feeding 10 lamps, is driven by belt from an Edison motor, whose energy is transmitted electrically from the large Edison dynamos. The second is larger, and is driven direct by belt from the main shaft. It supplies 24 horse-power for 24 Jablochkoff lamps. The whole of this second group, which was put down two and a-half years ago, is driven by a large horizontal two-cylinder Corliss engine, non-compound. The speed is 68 revolutions per minute, and the horse-power 300. The diameter of each cylinder is 19 inches. Besides this there is a four-cylinder compound engine, giving 120 horse-power, and driving four other small Edison dynamos. The boilers in both these installations are of the multitubular Root type, and ample provision for extension has been allowed for, especially at the Palais Royal, where the boiler-power is equal to many times the present rate of steam consumption.

Friday, August 30th.

Friday being the last day of the Section meetings, there was a large attendance in each room, even the Physiological Section sitting for no less than two and three-quarter hours and listening to three Papers. This Section has met altogether three times, but has not been at all well supported.

In Section I., M. Goldhammer gave as the result of his experiments on nickel that the electrical resistance in a magnetic field is proportional to the square of the intensity of the magnetic induction. M. Stoletow described some experiments on electro-actinic discharges; and M. Pilleux gave an interesting communication on the law of thermo-electric couples. The result of his investigation is the following equation:—

$$E = (K - K')(T' - T)$$

where E is the electromotive force generated in consequence of the difference of temperatures T and T′ of the two junctions, and where K is the mean coefficient of variation of electric conductivity of one of the metals and K′ that of the other.

Sir W. Thomson denied that this law was accurate for pure metals.

The other communications in this Section were without much special interest.

In Section II. M. Faure read a long and interesting Paper on the theory of the chemical action in secondary batteries.

M. Faure, after paying a graceful tribute to the memory of M. Planté, indicated what he considered to be a perfect accumulator, namely, one composed of two unattackable plates uniformly covered with active material. The active material, he said, played the *rôle* of conductor, and, according to the makers of batteries, the portion which acts in this capacity was from three to six times greater than that which took part in the chemical reactions. The accumulators of the Planté type had the advantage of possessing a relatively large mass of material which could be electrolysed, but the support

Digitized by Google

was liable to be attacked, although the use of antimony overcame this drawback. He thought it quite possible to estimate accurately the capacity of any battery from the weight of its active material so long as the material was in close contact with its support and facilitated the formation of parallel lines of current. In order to properly estimate the value of reduced lead as a positive substance, M. Faure said that we must bear in mind the remark of M. Drzewiecki that there is a great difference of potential between solid and reduced lead. This difference was, he thought, due to the fact that the lead was so finely divided. If we reduce oxide of antimony by electrolysis a powder is obtained, which, when dried, explodes on being struck, liberating much heat. This heat represents the work done in effecting the molecular division. Something analagous, M. Faure said, must take place in the case of reduced lead, the work done being represented in the shape of potential. We have, on one hand, a highly electro-positive body, and on the other a body which furnishes oxygen freely. Sulphuric acid no doubt facilitates the liberation of oxygen, but we must not lose sight of the fact that the sulphating of the peroxide is, from the point of view of the generation of E.M.F., merely a local and deleterious action, In fact, two litharge plates plunged into acid do not give a current, although local sulphating takes place, hence the heat resulting from the oxidation and sulphating of the reduced lead is a measure of the maximum available energy, and all that takes place on the peroxide plate only diminishes this quantity.

Mr G. Roux then read a Paper describing a method of keeping constant the potential of compound-wound dynamos, which from one or other cause have to be run at a speed different from that for which they have been calculated and constructed. The method is a very simple one, and consists merely in taking a shunt between the ends of the series coils and inserting in this shunt a resistance which may be varied according to the speed at which it is desired to run the dynamo. The higher the speed rises above the normal speed for which the winding has been calculated, the lower must this shunt resistance be made, in order to diminish the effect of the series coils. The resistance thus inserted may be regulated either by hand or automatically by the steam-engine governor. The dynamo winding must be made suitable for the *smallest* speed desired. Although this device is by no means new, the Paper provoked a good deal of discussion.

M. Ch. Jacquin then gave in *résumé* a Paper "On Characteristic Curves for Transformers," these curves giving the current, the energy received and that discharged, and therefore also the efficiency, in terms of the resistance and of the current in the secondary circuit.

Prof. G. Forbes then described his well-known meter for measuring both continuous and alternating-currents.

M. Decaux described a series of interesting experiments, comparing the action of sunlight and that of electric light on the water and oil colours used in dyeing and in painting.

M. M. Richard then described several instruments made by his firm, but his descriptions might have been shorter and more comprehensible if he had brought the instruments with him. It seemed rather severe on an audience gathered together for the purpose of discussing electrical matters of general importance, and whose last hours were drawing to a close, to compel them to listen to long, sketchy and rambling references of various instruments whose concrete existence was left entirely to the imagination of the meeting. The result was that an extra afternoon sitting had to be arranged for at two o'clock in order to discuss the definitions of the various quantities coming into the calculation of alternate-current machines and transformers. The results of this discussion, as embodied in the votes of the Section, were as follows :—

1. The name "quadrant" was adopted for the unit co-efficient of induction. This is equal to 10^9 C.-G.-S. units, and is the same as the "secohm" of Messrs. Ayrton and Perry.

2. A special name is not needed for the time-constant L/R.

3. The name "period" is to be applied to the time of a *complete double* (plus and minus) oscillation.

4. The number of periods or of complete oscillations per second is to be called the "frequency."

5. The *mean* current is to be defined in the ordinary way, namely, by $\frac{1}{T}\int_0^T i\,dt$, where i is the variable current and T the complete period.

6. For $\frac{1}{T}\sqrt{\int_0^T i^2\,dt}$ no name could be agreed upon, those suggested being the "virtual," "equivalent," "mean quadratic," "practical," "useful," "effective," "thermal," and "indicated" current.

7. The "apparent" resistance or "resistance fictive" of a circuit is the factor by which $\frac{1}{T}\sqrt{\int_0^T i^2\,dt}$ must be multiplied in order to obtain $\frac{1}{T}\sqrt{\int_0^T E^2\,dt}$ when E is the variable E.M.F. This is more simply stated thus :—

The "apparent" resistance is $\sqrt{\frac{\int_0^T E^2\,dt}{\int_0^T i^2\,dt}}$.

8. In secondary batteries that plate which is connected to the positive-pole of the charging dynamo, and which becomes the positive-pole during the discharge, is to be called the *positive plate.*

In Section III., after some further discussion in continuation of that of the previous day, it was decided that the Congress should recommend that the normal length of the conversation allowed on public inter-urban telephonic lines should be three minutes, and "inter-urban" was defined so as to make it apply to communication between two members or public stations which are parts of different groups.

A proposition of Mr. J. Maier's that the word "phone" should be adopted to mean "telephonic message" was discussed without any resolution being come to, one member proposing the word "telepheme."

Other Papers were read upon "The Influence of Telephony on Telegraphy" (treated from a financial point of view), on "The Multiple Printing Telegraph of M. Baudot," and "On Signalling Time by Telegraphic Wires."

There were two excursions in the afternoon, the first a short visit to the "Instruments of Precision" in the Exhibition, and the second a visit to the electric light installation at the St. Lazare railway station. The latter was well attended. There are here six continuous-current Gramme machines, newly put down and of the most recent construction. In a subsequent issue drawings and detailed dimensions of these machines will be given. They run at 500 revolutions per minute, and give each 450 amperes at 80 volts, or 36 kilowatts. The magnet cores and pole-pieces are of cast iron, and the brushes are divided into eight sections. These are driven by three horizontal steam engines built by Lecouteux and Garnier, running at 180 revolutions per minute with steam at 6½ atmospheres, and each supplying about 150 horse-power. The lamps are all arc lamps of the Cance type.* M. Cance himself guided the party in this visit, and took much trouble in explaining the arrangements, which appear to be in every respect admirable.

Saturday, August 31.

The closing meeting of the Congress took place on Saturday morning at ten o'clock, in the "Salle des Conferences," at the Trocadero. M. Mascart presided, with Sir William Thomson and Mr. Preece at his right and left hands, and supported by the Presidents of all the Sections. He announced that there would be another privileged ascent of the Eiffel Tower on the following morning, and asked for exact copies of all the Papers read in the Sections to be sent to the Secretary before the 15th September, in order that the *Comptes Rendus* of the proceedings might be sent to the members without undue delay. He also asked them to send to the Secretary, at 44, Rue de Rennes, the address to which each member wished his copy of the *Comptes Rendus* to be sent.

* See *Electrician*, September 28, 1888, p. 680.

Digitized by Google

Mr. Edison was then elected a Vice-President of the Congress. Mr. Edison has not been able to attend any of the meetings, but he has written to the President to express his wish that his name should be associated with it.

M. Carpentier then read a short Report on "Standard Ohms constructed in consequence of the Decisions of the Congress of 1881." The results of experiments made by MM. Benoit and Carpentier have shown that the mercury standards are absolutely permanent; the differences observed over many years are within the limits of the errors of observation.

The next business was the presentation of the recommendations of the various Sections and Committees that have been appointed by the Sections. The Committee on "Units" recommended that—

1. The practical unit of work should be the Joule = 10^7 C.-G.-S. units, and also equal to the work done in one second by one ampere in one ohm.

2. The practical unit of power should be the Watt = 10^7 C.-G.-S. units, and also equal to one joule per second.

Both these recommendations were confirmed by the unanimous vote of the Congress, the latter being combined with the adoption of the kilowatt as a more useful unit for industrial purposes than the "horse-power." "The bougie-decimal" adopted by Section I. at its Tuesday's meeting was also approved by a unanimous vote, as were also the names "quadrant," = 10^9 centimetres, "period," "frequency," "mean-current," and "apparent resistance" already mentioned in this report as having been settled upon in Section III. on Friday. The "effective current" and "effective electromotive force" were adopted as the names to be employed for the "square root of the mean of the squares" of the current and of the electromotive force.

The recommendation of Section II. to call the "positive plate" of an accumulator that which is connected to the positive pole during charge, and which is itself the positive pole during discharge, was also confirmed by a unanimous vote, as was also the recommendation to use the method proposed by M. Crova and approved by Section II. as the means of determining the degree of incandescence of a lamp. We shall describe this method in detail in a later issue.

The recommendations of Section III., to the effect that the double wire should be used on telephonic urban circuits and inter-urban lines, the term "inter-urban" being defined as has been already explained in this report, was also adopted.

With regard to the fixing of three minutes as the limit of conversations on inter-urban lines, the Congress came to the very sensible determination that this was too much of a pure business matter to be a proper subject for decision by the Congress as a whole, and that it must remain simply as a recommendation of Section III.

The President, before closing the Congress, said that they all felt regret that it was necessary to separate again after a meeting that has appeared much too short. The response to the invitations that the organisers had issued had surpassed their expectations, and the meeting had proved that there existed a general sentiment of scientific concord. He offered, in the name of the Congress, its thanks to the illustrious *savant* who has combined the highest scientific speculations with the study of practical affairs; who has transformed our electrical measuring instruments; has sustained with unconquerable faith the courages of those engaged in the gigantic enterprise of transatlantic cables; while he has also invented transmitters and receivers which, after thirty years of use, have remained almost unmodified; whose compass and sounding apparatus, now everywhere adopted, have been of great benefit to humanity; and who has guided the reforms proposed by the British Association and afterwards adopted by the Congress. The name of Sir William Thomson was on all lips, and he was beloved by all who had the privilege of his intimacy. (This eulogy was received with an extremely remarkable demonstration of enthusiastic assent.) He then referred to the immense extension of electrical activity, and declared that the precision of the language of electricity has led to great advance in the knowledge of natural phenomena. The resolution to apply a special name to each quantity used in practice has contributed in an incalculable degree to the spread of scientific knowledge, this inseparable connection between language and thought being only one particular application of the sovereign law which rules the intellectual development of man. The definitions of the Joule, the Watt, and the Quadrant will be all the more readily accepted because they simply confirm already established usage.

Alternating currents, which have been familiarly known ever since Faraday's first discovery of induction, appeared at first to be insusceptible of useful application. After forty years of experiment, the memorable discoveries of Paccinotti and Gramme gave us the means of cheating Nature, so to speak, so as to obtain all the effects of continuous currents. During recent years, however, alternating currents have suddenly come into favour, and their applications have become numerous. There is hope that this Congress had contributed towards making more precise our ideas, and toward the future avoidance of ambiguities regarding these.

Some members might think that the Congress had not settled enough. Its decisions, however, can only be carried into execution by the help of persuasion, and, therefore, moderate measures agreed to by both those who are impatient for more rapid advance, and those who are more conservative in their ideas, will unite the support of all, and give the resolutions of the Congress more weight and authority.

The great nation of the United States, who have taken so important a part in this Universal Exhibition, have already fixed 1892 as the date of the next *réunion*, and the American Institution of Electrical Engineers invites to that meeting the scientists and the engineers of the Old World. We can only thank them for this invitation, and offer our best wishes for the new bonds that are to be established between the two shores of the Atlantic.

The President of the Republic had charged him to be the interpreter of the great interest he attaches to their labours, and of his regret at not being able to receive personally the whole Congress. He would receive the Bureau of the Congress on Monday, who would express to him in name of all the members their respectful gratitude.

Sir William Thomson, who was received with great cheers, moved a vote of thanks to M. Mascart for the energetic and skilful way in which he had performed the duties of President, and attributed to him the honour of all the success which has attended the meeting of the Congress. The meetings had given him (Sir William) much pleasure, and the results would be useful to the industry. He felt profoundly grateful for the manner in which M. Mascart had referred to him and to his past work, and for the generous appreciation with which the meeting had received M. Mascart's words. The vote of thanks to the President was carried by acclamation, and the Congress was then declared to be closed.

On Monday the Committee of the Congress journeyed to Fontainebleau, where they were received by President Carnot and entertained at luncheon. We may add that out of the long series of Congresses which have been held at Paris during the period of the Exhibition this is the only occasion upon which such an honour has been conferred. The English representatives present were Sir William Thomson and Mr. W. H. Preece.

The following is a list of the English and American members of the Congress :—

John Aylmer, Richard Aylmer, — Barker, Graham Bell, J. D. Bishop, G. B. Burgess, J. De Castro, R. E. B. Crompton, B. M. Drake, L. Drugnah, T. A. Edison, Prof. G. Forbes, Sir Douglas Galton, D. Goldhammer, J. M. Gorham, Ch. G. Gümpel, G. A. Hamilton, E. W. Hammer, C. Hering, Prof. D. E. Hughes, Gisbert Kapp, A. Macfarlane, C. L. Madsen, C. O. Mailloux, Maquaire, W. H. Massey, J. F. Moulton, F. W. Parker, T. Parker, F. J. Parsons, Prof. J. Perry, C. E. Pitman, W. H. Preece, E. W. Rice, Prof. Rowland, John Smith, R. H. Smith, A. Snell, W. H. Snell, Ch. E. Spagnoletti, Aug. Stroh, A. A. C. Swinton, Prof. Silvanus P. Thompson, Sir William Thomson, F. R. Upton, R. W. Wallace, F. H. Webb, Major-General C. E. Webber, A. G. Webster, Joseph Wetzler, H. D. Wilkinson, Joseph Willot.

The following Governments and Societies were also represented :—

The Ministry of Marine, the Société Centrale du Travail Professionnel the Comité Italien, the Japanese Imperial Commission, and the Governments of Belgium, Brazil, Chili, Greece, Hawaii, Italy, Japan, Mexico, and Spain.

THE KILOWATT.*

BY W. H. PREECE.

In a pamphlet printed in 1881 for the information of the Electrical Congress, then sitting in Paris, I wrote :—

The *erg* is the C.-G.-S. unit of work, but it is so small that it must be multiplied a million times for practical purposes : hence the megerg = 10^6 ergs. Sometimes it is multiplied by 10^{10} and called "ergten." This multiple is more convenient than the megerg, since it approximates very closely to the horse-power of Watt, which is 550 foot-pounds per second. One horse-power is equal to $\cdot746 \times 10^{10}$ ergs. It would be a great benefit to science to replace the horse-power or the *cheval-vapeur*, which are both arbitrary and without basis, by a more scientific unit, and no unit could be more advantageous than the "ergten" (ergdix), which might be called the watt.

Foot-pound	=13·56 megergs	= ·00135	ergten.
Kilogrammetre..	=98·1 ,,	= ·0098	,,
Force de cheval.	=7360 ,,	= ·736	ergten per second.
Horse-power ...	=7460 ,,	= ·746	,, ,, ,,

This proposal was not formally submitted to the Congress, for they had the more important task to determine—the adoption of the C.-G.-S. system of electrical units.

In 1882 William Siemens proposed to call the one-thousandth part of this unit—that is the product of an ampere and a volt, or the volt-ampere—a *watt*, and it was found so convenient to give a short, clear name to a unit which was then in constant and incessant practical use that the watt was eagerly adopted by electricians, and was accepted by the Committee of the British Association in 1888 as the unit of the rate of doing work or of *power*.

It is questionable whether it would not have been better to have adopted my proposition, in which case the volt-ampere would have been the *milliwatt* in preference to the smaller number ; but the volt-ampere or watt having been so universally accepted as a convenient unit, the "erg-ten" becomes the *kilowatt*.

Hence I submit to this Congress that the watt or the power expended by a current of one ampere in a conductor whose ends differ in potential by one volt—that is, 10^7 C.-G.-S. units of work per second—be taken as the unit of power. The result will be that as this is a mechanical and not an electrical unit, when mechanicians comprehend fully the simplicity, the scientific accuracy, and the universality of the system of units adopted by electricians, they will find that the *kilowatt* is a far superior practical unit of power to the meaningless and absurd "horse-power," or to the "force de cheval." The horse-power differs in different countries ; the kilowatt is everywhere the same. The horse-power involves the use and recollection of constants ; the kilowatt contains in its own name the only constant that is wanted. Its use will simplify all calculation of efficiency, for the energy produced and expended in all parts of a complete system are expressed in precisely the same language, and are measured in the same units.

The unit of electrical energy expended for commercial purposes in England is the amount of energy expended by a kilowatt per hour, and hence electric meters measure in kilowatt-hours, and the public employing the current for electric lighting or for the transmission of power pay so much per kilowatt-hour. The kilowatt admits of a very simple abbreviation—"kwt."—and it is especially useful in indicating the capacity of dynamos. If a dynamo is of *x*-kwts., we know at once the engine required to drive it and the amount of electrical energy it will deliver.

Power.

The watt is a mechanical unit, it is 10^7 ergs per second ; hence as one foot-pound per second = 1·356 watts, and a horse-power is 550 foot-pounds per second, therefore a horse-power = 550 × 1·356 = 746 watts. Similarly, a force de cheval, or 75 kilogrammetres per second = 736 watts.

C.-G.-S. unit	1 erg per second.
Watt.....	10^7 ergs per second.
Foot-pound per second	1·356 watts.
Kilogrammetres per second	9·81 watts.
Force de cheval	736 watts.
Horse-power	746 watts.
Kilowatt.....	10^{10} ergs per second. 1,000 watts = 10^3 watts. 1·358 force de cheval. 1·3405 horse-power.

The progress of electrical science has been greatly facilitated by the adoption of the C.-G.-S. system of practical units by the Electrical Congress of 1881, and the fusion of electrical and mechanical science, which is imperative in the further developments and applications of electrical energy, will be greatly benefitted by the adoption of a common and accurate mechanical unit by this Congress of 1889.

* Paper read before the International Electrical Congress.

THE STRIKING OF THE EIFFEL TOWER BY LIGHTNING.*

BY M. MASCART.

Several of my colleagues have thought that it would be interesting to give a few details relating to the striking of the Eiffel Tower on the evening of the 19th August last, an event which has been the subject of several exaggerated accounts. I have taken these details from the report drawn up by M. Foussat, chief of the electrical service, who was on the upper platform during the storm.

The tower is provided with a central rod projecting from the summit, and with eight oblique rods situated on the balustrade of the third platform. The bronze point tipped with platinum, which was orginally at the end of the central rod, had been taken off a few weeks previously on account of its shaky condition.

At 9:40 p.m. the principal lightning conductor at the summit was struck, with a noise like that of two small cannons. Some red drops, due probably to the combustion in the air of volatised iron, fell from the point, and it was subsequently found that the screw at the tip of the conductor was so scored that it was necessary to file it before the set of points could be replaced. A glow, accompanied by considerable crackling, was noticed several times on the rods attached to the platform. The lighthouse-keeper was attending to his apparatus, two men were working the projectors on the platform, and M. Foussat was leaning against the handrail watching the rod attached to the lighthouse. It is worthy of notice that none of these four persons felt the slightest shock at the moment when the flash struck the conductor. However, on account of the heavy rain and the possibility of danger if a second flash struck the tower, the projectors were extinguished, and the three persons on the platform sought shelter in the laboratory. At this moment a highly electrified cloud descended on the top of the tower. It was this doubtless which gave many people in Paris the idea that the top of the tower after the flashes seemed to be enveloped in an electric glow of such intensity that it completely eclipsed the light of the projectors. I should add that the meteorological instruments at the bottom of the conductor experienced no injury whatsoever. This flash was, in short, in conformity with all known facts, and showed moreover that the earth connection was perfect and the tower absolutely safe.

A SUMMARY OF THE DIFFERENCES BETWEEN POSITIVE AND NEGATIVE ELECTRICITY.

In a recent number of *La Lumière Electrique*, M. Decharme sums up in the short article following the principal differences which have been shown to exist in the behaviour of positive and negative electricity :—

It has been shown by Wachter in the *Journal de Physique* that "in a conductor of high resistance the section which is at a mean potential is not symmetrical with respect to its two terminals, and that the higher the resistance of the conductor the nearer to the negative terminal is this point of mean potential." With regard to mechanical effects, it is evident by Lichtemberg's figures, pierced cards, &c., that in discharges of static electricity solid or liquid substances are generally carried towards the – pole and away from the + pole, or, at any rate, more abundantly in this direction than in the other. The action of electrified points on flames may be summed up by saying that negative electricity attracts and positive electricity repels them. An electrified flame is also more powerfully attracted than a flame upon which it induces electricity. It is also well known that there is a decided difference of temperature in the poles of the voltaic arc. In air the + electrode is heated to incandescence, while the – electrode is at a lower temperature. On the other hand if the arc is struck in highly rarefied air, the – electrode attains the temperature of melting platinum, while the + electrode is relatively cool. If one of the electrodes is pointed and the other flat, the point becomes entirely incandescent if it is positive, but it only becomes hot at its extreme tip if it is negative. M. Semmola has devised a very striking experiment to show this phenomenon in an indirect way. He uses a fine point, made of bismuth and antimony, and thus forms a thermo-electric couple. If this point is connected to the conductor of an electric machine, a galvanometer placed in the circuit immediately shows the rise in temperature of the point, and especially so when the point is negative. When a rather long electric spark takes place across an air gap, it sometimes spreads out near the middle, always however closer to the – pole than to the + pole. When the gap is lengthened, the spark frequently assumes an arborescent character, and it is observed that the lateral

* *Comptes Rendus*, Vol. CIX., No. 9.

Digitized by Google

branches are all directed towards the – pole, showing clearly that there exists an electric-tension in the body of the spark itself. Moreover, when wires are fused by an electric discharge, the fused metal is projected laterally. The hook-like shape of the electric-spark obtained from the rheostatic machine of M. Gaston Planté shows that the electricity coming from the + pole meets the electricity coming from the – pole at a point close to the latter.

Photographs of sparks exhibit curious differences, characteristic of the two electricities. In 1877, M. A. Righi published a lengthy memoir, entitled, "Ricerche Sperimentali sulla Scariche Elettriche," in which are given numerous illustrations of the electric spark, copied from photographs taken under different conditions by the author. The characteristics of the two discharges are here clearly delineated; the positive discharges being spread out, the negative being more concentrated. The same memoir also contains an illustrated description of the various forms taken by the electric spark in air and in liquids, showing most perfectly the difference in shape and colour presented by the two electricities.

As to the induction spark, it consists of two streams and an aureola. In air, at ordinary pressure, the positive and negative brushes display differences arising from the inequality of potential at the moment of discharge. These differences become less accentuated as the air becomes more rarefied. The hook-like brush shows the same peculiarities as the spark. In a partial vacuum the difference between positive and negative electricity is very marked by the colour of the glow around the two poles, by the shape of this glow, and above all—and this more especially when an induction coil is used—by the presence of striæ. These phenomena are much affected by the medium. In a complete vacuum the purple glow seems to move in the same direction as the positive discharge.

Another fact, not less important, which ought to be kept in mind is that in vacuum tubes and with sufficiently powerful E.M.F.'s, the striæ are always turned in the same direction with the convex side towards the – pole. This phenomenon is analogous to that which is presented where a gas makes its way through a liquid, which it never does in a continuous stream, but always in bubbles more or less large according to the pressure. In the same way electricity, when it penetrates a gaseous medium more or less rarefied, does not pass through it in an unbroken stream, but in a vibratory manner. In this way perhaps the phenomenon of striæ can be explained mechanically, for it is produced with continuous currents as well as with intermittent or alternating currents.

In air at ordinary pressure we can say, so far as regards potential, loss of charge, and propagation, that negative electricity is always at a lower potential than positive electricity, that a negative charge is more rapidly dissipated than a positive, that negative electricity is more easily propagated than positive. The contrary holds good in a disruptive discharge, when positive electricity has the greater tendency to discharge though the air. In rarefied air these differences disappear, whether high potentials or large currents are employed. There is, therefore, nothing absolute about these tendencies, since they depend entirely on the experimental conditions. This, however, does not render these differences more easy of explanation.

In physiological effects the direction of the current is of supreme importance. When a continuous current, acting on a motor nerve, is propagated in the same direction as the nerve ramifications, *i.e*, from the centre outwards, it produces a contraction at the moment of closing the circuit and a sense of pain at the moment of breaking the circuit, and the direction of the current being reversed, a painful sensation on closing and contraction on breaking the circuit. When we operate on a sensory nerve the opposite takes place. Finally, if a current paralyses a muscle, we need only reverse its direction in order to restore its contractile power. We cannot do better than compare the contraction of a muscle at the moment of breaking the circuit to the recoil which takes place in a long water pipe when the flow of water is suddenly arrested by the closing of a tap.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 24, 1889.

Following closely upon the meeting of the National Electric Light Association at Niagara Falls came the Convention, last week, of the Edison Illuminating Companies. While the former is a large body which sits with open doors and invites the public into its confidence, the latter is a close organisation whose proceedings are conducted in secret behind barred doors. I would not undertake to say that the bars are actually up and the bolts shot, but it is nevertheless a fact that nobody is allowed to attend unless he has very good right and reason for doing so. The fact is that the Edison Association may be looked upon as a large family wherein all the parties, while they may not have the same ideas, have pretty much the same interests in common, and hence questions are discussed which could not be treated if the deliberations were to be made public. There is, on the part of some Edison men, a feeling that this secret conclave business might be advantageously given up, and that the members might well join the larger body, while all private questions could still be discussed in some private way. Be that as it may, it has been determined to hold the meetings annually hereafter instead of semi-annually. This recent meeting at the Falls is the first of the annuals, and so the Association will not convene again until August of next year. In this respect it might, perhaps, be well if the National Electric Light Association followed the example of the smaller body, for it seems as though the National Electric, being well able to dispose of all its important business at one meeting a year, occupies its ample leisure at the semi-annual meetings by quarrelling and quibbling over constitutional points which are rarely of thrilling interest, but which seem calculated always and everywhere to promote dissension and bitterness. The work of the Edison Association this year appears to have been up to the standard, and as far as can be gathered, some papers presented were of quite general interest. For example, Mr. A. E. Kennelly, the electrician of the Edison Laboratory, brought before the meeting some important results obtained with regard to investigations into the heating of conductors by electric currents. This subject was first suggested to the Edison Standardising Bureau by Captain William Brophy, of the New England Insurance Exchange, and proved to be one upon which very little accurate information was obtainable. Mr. Kennelly therefore adopted the course of taking some 24 wires of different sizes, placing them in pannelling, and passing various currents through them, the highest being 300 amperes, which was considered a maximum for general interior work. Observations were made as to the temperature resulting from these various currents. The highest temperature reached was 100deg. Centigrade, or about 180deg. Fahrenheit, above the surrounding air of the room. This was reached by No. 26 B.W.G. wire with 9 amperes of current. As the wires grew bigger and bigger the temperature lowered correspondingly with the same current, until with the largest wire only 40 degrees Centigrade was reached with 300 amperes. By taking these results, they show what temperature could be reached by any current on a given size of wire under ordinary conditions. As was pointed out, the important question arose as to what might be considered a safe temperature. The Paper which was presented by Mr. Kennelly on the subject embodied valuable data, and will, it is to be hoped, become public property. Another interesting question that was presented was that of the maximum of efficiency of incandescent lamps for central-station work. It will be remembered that some time since Mr. J. W. Howell, in a Paper read before the American Institute of Electrical Engineers, enunciated the law that the point of maximum efficiency is reached when the lamp bills are about 15 per cent. of the total expenses of the station. This law was analysed in a Paper by Mr. Carroll, who pointed to certain conditions which he considered should modify the operation of such a law, and would thus render it an equitable basis for the calculation of conditions to govern in central-station practice. Mr. Howell will be invited to reconsider the subject, and, if possible, formulate a modification of his Paper in the shape of practical rules for the use of managers of Edison central stations, so that they may be enabled to judge just when the various factors that have to be taken into account are at the right point. A very interesting subject brought up was that of the use of high potentials as an adjunct to Edison central station work. Mr. Gilbert, of Detroit, offered a resolution stating that the Edison local companies had suffered in their business for the lack of an efficient and inexpensive arc-lighting system, an arc lamp which could be put on an incandescent three-wire system, and a flexible method of covering the territory so that the remote districts could be covered in some other way than by the three-wire system. Mr. Jenks, of the parent company, presented an able Paper or report touching on the points raised in this resolution, and discussing the various ways in which the Edison stations might be better enabled to meet the sharp competition which

Digitized by Google

they are naturally subjected to. As was pointed out, if the Edison manager let the arc-light business alone, somebody was sure to come along and supply that want; but it did not take many months before the arc-light station found that it was necessary and desirable to go into the incandescent lighting business, and hence competition arose which might be avoided, or if not avoided, might be successfully met. Mr. Jenks made the interesting statement that Edison direct-current transformers would now be supplied to stations desiring to go into long-distance work. There are two varieties of these machines in prospect. In the one now operated they have a motor and dynamo combined in one, the armature being provided with two independent sets of coils, a commutator at each end, and no pulley. The high-pressure current of a thousand to twelve hundred volts from a municipal dynamo is received on one commutator, and the low-pressure current of one hundred to one hundred and twenty-five volts is sent out from the other. The machine is regulated from the primary generator. Five sizes are proposed, ranging from 60 to 640 amperes. Mr. Jenks also stated, and he was corroborated by Mr. Herrick, the new vice-president of the Edison General Electric Company, that the company will soon be prepared, in cases where a comprehensive series-arc system is desired, either to furnish, or definitely recommend and endorse, some efficient economical system, and, if desirable, superintend its installation. There can be no doubt about it, that many Edison stations will soon be found doing a long-distance electrical business for lighting and power. With regard to the motor business, it was stated that the three New York central stations are now delivering every day upwards of 500 horse-power current to motors, and that in Boston about 700 horse-power is being delivered, an addition of 150 horse-power since June 1st. Among other interesting subjects brought up before the Convention were the question of grounding the neutral conductor in 3-wire systems, the location of grounds in underground tube systems, the improvements in the Edison chemical meter, and the ingenious new method of running interior wires through non-conducting and non-inflammable tubes placed throughout a building so that the conductors can be installed after the building has been completed. The Association also took up the question of mutual insurance, and a committee recommended that as many central station officials as possible, in order to secure lower rates than are granted by the regular stock companies, agree in writing to transfer certain portions of their insurance to mutual companies at one per cent.

Some few years ago, one of the doughtiest of the opponents of electric lighting was General Hickenlooper, a leading representative of gas interests in Cincinnati. He sifted the entire technical press of the world for reports of trouble with electric light plants, published columns of "accidents" in the daily papers, and even issued pamphlets on the subject. But the gallant general has now shown himself to be something more than a Mrs. Partington trying to sweep back the Atlantic with a broom. He has recognised the fact that the electric light has come to stay, and he now proposes to make it a welcome guest. His recantation takes the shape of a splendid new electric light station for Cincinnati, and so well satisfied is he with the prospects that he has had the plans made to include a duplicate station to be built as soon as possible after the first has started. This change of front is not singular or unique, however, for every week record is made in the journals of some gas company or other that has bought electric lighting apparatus, or that seeks power to go into the business.

We need not wonder that the business is attractive when we are told that in one plant started for arc-lighting some few years ago in a city of about 100,000 inhabitants on a capital of $80,000, the net yearly profits each year have equalled the original cost of the plant, and that a "cash down" offer of $260,000 has been made for the plant as a going concern. In other words, the plant to-day represents a return of $580,000 for the original investment of $80,000. This is on arc-lighting. The prices are not as good for arc lights as they once were, but they are still living prices, while the motor industry has grown up as an additional source of income. One superintendent of a station supplying about 125 horse-power of current for motors stated recently that his profit figures out about 38 per cent. on the original investment.

A special committee that has been investigating the subway explosions now so frequent in this city, reports that the trouble all lies with the gas companies, whose mains are leaky. It is recommended that the subways be steadily and regularly kept free from gas by means of blowers, such as are already in use; and further, that some competent Board be organised that shall have jurisdiction over all underground work of whatever character, so that the various services and interests shall not clash, and that the streets shall be saved from utter wreck. Even if a Board be appointed, I shall not be surprised to see New Yorkers starting a Street Preservation Society. It is badly needed.

CORRESPONDENCE.

THE ELECTROMAGNETIC EFFECTS OF A MOVING CHARGE—III.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In two previous communications under the above title (*The Electrician*, November 23, 1888, p. 83, and December 7, 1888, p. 147) I have discussed this matter. Referring to the case of steady rectilinear motion, I gave a description of the result when the speed of the charge exceeds that of light, obtained mainly by general reasoning, and stated my inability to find a solution to represent it. The displacement cannot be outside a certain cone of semi-vertical angle whose sine equals the ratio v/u of the speed of light to that of the charge, which is at the apex.
